# COMPARING THE CLOSED ALMOST DISJOINTNESS AND DOMINATING NUMBERS 

DILIP RAGHAVAN AND SAHARON SHELAH

#### Abstract

We prove that if there is a dominating family of size $\aleph_{1}$, then there is are $\aleph_{1}$ many compact subsets of $\omega^{\omega}$ whose union is a maximal almost disjoint family of functions that is also maximal with respect to infinite partial functions.

## 1. Introduction

Recall that two infinite subsets $a$ and $b$ of $\omega$ are almost disjoint or a.d. if $a \cap b$ is finite. A family $\mathscr{A}$ of infinite subsets of $\omega$ is said to be almost disjoint or a.d. in $[\omega]^{\omega}$ if its members are pairwise almost disjoint. A Maximal Almost Disjoint family, or MAD family in $[\omega]^{\omega}$ is an infinite a.d. family in $[\omega]^{\omega}$ that is not properly contained in a larger a.d. family.

Two functions $f$ and $g$ in $\omega^{\omega}$ are said to be almost disjoint or a.d. if they agree in only finitely many places. We say that a family $\mathscr{A} \subset \omega^{\omega}$ is a.d. in $\omega^{\omega}$ if its members are pairwise a.d., and we say that an a.d. family $\mathscr{A} \subset \omega^{\omega}$ is $M A D$ in $\omega^{\omega}$ if $\forall f \in \omega^{\omega} \exists h \in \mathscr{A}\left[|f \cap h|=\aleph_{0}\right]$. Identifying functions with their graphs, every a.d. family in $\omega^{\omega}$ is also an a.d. family in $[\omega \times \omega]^{\omega}$; however, it is never MAD in $[\omega \times \omega]^{\omega}$ because any function is a.d. from the vertical columns of $\omega \times \omega$. MAD families in $\omega^{\omega}$ that become MAD in $[\omega \times \omega]^{\omega}$ when the vertical columns of $\omega \times \omega$ are thrown in were considered by Van Douwen.

We say that $p \subset \omega \times \omega$ is an infinite partial function if it is a function from some infinite set $A \subset \omega$ to $\omega$. An a.d. family $\mathscr{A} \subset \omega^{\omega}$ is said to be Van Douwen if for any infinite partial function $p$ there is $h \in \mathscr{A}$ such that $|h \cap p|=\aleph_{0} . \mathscr{A}$ is Van Douwen iff $\mathscr{A} \cup\left\{c_{n}: n \in \omega\right\}$ is a MAD family in $[\omega \times \omega]^{\omega}$, where $c_{n}$ is the $n$th vertical column of $\omega \times \omega$. The first author showed in [3] that Van Douwen MAD families always exist.

Recall that $\mathfrak{b}$ is the least size of an unbounded family in $\omega^{\omega}, \mathfrak{d}$ is the least size of a dominating family in $\omega^{\omega}$, and $\mathfrak{a}$ is the least size of a MAD family in $[\omega]^{\omega}$. It is well known that $\mathfrak{b} \leq \mathfrak{a}$. Whether $\mathfrak{a}$ could consistently be larger than $\mathfrak{d}$ was an open question for a long time, until Shelah achieved a breakthrough in [4] by producing a model where $\mathfrak{d}=\aleph_{2}$ and $\mathfrak{a}=\aleph_{3}$. However, it is not known whether $\mathfrak{a}$ can be larger than $\mathfrak{d}$ when $\mathfrak{d}=\aleph_{1}$; this is one of the few major remaining open problems in the theory of cardinal invariants posed during the earliest days of the subject

[^0]DILIP RAGHAVAN AND SAHARON SHELAH
(see [5] and [2]). In this note we take a small step towards resolving this question by showing that if $\mathfrak{d}=\aleph_{1}$, then there is a MAD family in $[\omega]^{\omega}$ which is the union of $\aleph_{1}$ compact subsets of $[\omega]^{\omega}$. More precisely, we will establish the following:
Theorem 1. Assume $\mathfrak{d}=\aleph_{1}$. Then there exist $\aleph_{1}$ compact subsets of $\omega^{\omega}$ whose union is a Van Douwen MAD family.

The cardinal invariant $\mathfrak{a}_{\text {closed }}$ was recently introduced and studied by Brendle and Khomskii [1] in connection with the possible descriptive complexities of MAD families in certain forcing extensions of $\mathbf{L}$.

Definition 2. $\mathfrak{a}_{\text {closed }}$ is the least $\kappa$ such that there are $\kappa$ closed subsets of $[\omega]^{\omega}$ whose union is a MAD family in $[\omega]^{\omega}$.

Obviously, $\mathfrak{a}_{\text {closed }} \leq \mathfrak{a}$. Brendle and Khomskii showed in [1] that $\mathfrak{a}_{\text {closed }}$ behaves differently from $\mathfrak{a}$ by producing a model where $\mathfrak{a}_{\text {closed }}=\aleph_{1}<\aleph_{2}=\mathfrak{b}$. They asked whether $\mathfrak{s}=\aleph_{1}$ implies that $\mathfrak{a}_{\text {closed }}=\aleph_{1}$. As $\mathfrak{s} \leq \mathfrak{d}$, our result in this paper provides a partial positive answer to their question.

## 2. The construction

Assume $\mathfrak{d}=\aleph_{1}$ in this section. We will build $\aleph_{1}$ many compact subsets of $\omega^{\omega}$ whose union is a Van Douwen MAD family. To this end, we will construct a sequence $\left\langle T_{\alpha}: \alpha<\omega_{1}\right\rangle$ of finitely branching subtrees of $\omega^{<\omega}$ such that $\bigcup_{\alpha<\omega_{1}}\left[T_{\alpha}\right]$ has the required properties. Henceforth, $T \subset \omega^{<\omega}$ will mean $T$ is a subtree of $\omega<\omega$.

Definition 3. Let $T \subset \omega^{<\omega}$. Let $A \in[\omega]^{\omega}$ and $p: A \rightarrow \omega$. For any ordinal $\xi$ and $\sigma \in T$ define $\operatorname{rk}_{T, p}(\sigma) \geq \xi$ to mean

$$
\forall \zeta<\xi \exists \tau \in T \exists l \in A\left[\tau \supset \sigma \wedge|\sigma| \leq l<|\tau| \wedge \tau(l)=p(l) \wedge \operatorname{rk}_{T, p}(\tau) \geq \zeta\right]
$$

Note that if $\eta \leq \xi$ and $\operatorname{rk}_{T, p}(\sigma) \geq \xi$, then $\operatorname{rk}_{T, p}(\sigma) \geq \eta$, and that for a limit ordinal $\xi$, if $\forall \zeta<\xi\left[\operatorname{rk}_{T, p}(\sigma) \geq \zeta\right]$, then $\operatorname{rk}_{T, p}(\sigma) \geq \xi$. Also, for any $\sigma, \tau \in T$, if $\sigma \subset \tau$ and $\operatorname{rk}_{T, p}(\tau) \geq \xi$, then $\operatorname{rk}_{T, p}(\sigma) \geq \xi$. Moreover, if $\mathrm{rk}_{T, p}(\sigma) \nsupseteq \xi$ and if $\tau \in T$ and $l \in A$ are such that $\tau \supset \sigma,|\sigma| \leq l<|\tau|$, and $p(l)=\tau(l)$, then there is $\zeta<\xi$ such that $\operatorname{rk}_{T, p}(\tau) \nsupseteq \zeta$. Therefore, if there is $f \in[T]$ with $|f \cap p|=\aleph_{0}$, and if $\sigma \subset f$ and there is some ordinal $\xi$ such that $\operatorname{rk}_{T, p}(\sigma) \nsupseteq \xi$, then there is some $\sigma \subset \tau \subset f$ and some ordinal $\zeta<\xi$ such that $\operatorname{rk}_{T, p}(\tau) \nsupseteq \zeta$, thus allowing us to construct an infinite, strictly descending sequence of ordinals. So if $f \in[T]$ with $|f \cap p|=\aleph_{0}$, then for any $\sigma \subset f$ and any ordinal $\xi, \mathrm{rk}_{T, p}(\sigma) \geq \xi$. On the other hand, suppose that $\sigma \in T$ with $\operatorname{rk}_{T, p}(\sigma) \geq \omega_{1}$. Then there is $\tau \in T$ with $\tau \supset \sigma$ and $l \in A$ such that $|\sigma| \leq l<|\tau|, p(l)=\tau(l)$, and $\operatorname{rk}_{T, p}(\tau) \geq \omega_{1}$, allowing us to construct $f \in[T]$ with $\sigma \subset f$ such that $|f \cap p|=\aleph_{0}$.
Definition 4. Suppose $T \subset \omega^{<\omega}, A \in[\omega]^{\omega}$, and $p: A \rightarrow \omega$. Assume that $p$ is a.d. from each $f \in[T]$. Then define $H_{T, p}: T \rightarrow \omega_{1}$ by $H_{T, p}(\sigma)=\min \left\{\xi: \operatorname{rk}_{T, p}(\sigma) \nsupseteq\right.$ $\xi+1\}$.

Note the following features of this definition
$\left(*_{1}\right) \forall \sigma, \tau \in T\left[\sigma \subset \tau \Longrightarrow H_{T, p}(\sigma) \geq H_{T, p}(\tau)\right]$
$\left(*_{2}\right)$ for all $\sigma, \tau \in T$ with $\sigma \subset \tau$, if there exists $l \in A$ such that $|\sigma| \leq l<|\tau|$ and $p(l)=\tau(l)$, then $H_{T, p}(\tau)<H_{T, p}(\sigma)$.
On the other hand, notice that if there is a function $H: T \rightarrow \omega_{1}$ such that $\left(*_{1}\right)$ and $\left(*_{2}\right)$ hold when $H_{T, p}$ is replaced with $H$, then $p$ must be a.d. from $[T]$.

Definition 5. $I$ is said to be an interval partition if $I=\left\langle i_{n}: n \in \omega\right\rangle$, where $i_{0}=0$, and $\forall n \in \omega\left[i_{n}<i_{n+1}\right]$. For $n \in \omega, I_{n}$ denotes the interval $\left[i_{n}, i_{n+1}\right)$.

Given two interval partitions $I$ and $J$, we say that $I$ dominates $J$ and write $J \leq^{*} I$ if $\forall^{\infty} n \in \omega \exists k \in \omega\left[J_{k} \subset I_{n}\right]$.

It is well known that $\mathfrak{d}$ is also the size of the smallest family of interval partitions dominating any interval partition. So fix a sequence $\left\langle I^{\alpha}: \alpha<\omega_{1}\right\rangle$ of interval partitions such that
(1) $\forall \alpha \leq \beta<\omega_{1}\left[I^{\alpha} \leq^{*} I^{\beta}\right]$
(2) for any interval partition $J$, there exists $\alpha<\omega_{1}$ such that $J \leq^{*} I^{\alpha}$.

Fix an $\omega_{1}$-scale $\left\langle f_{\alpha}: \alpha<\omega_{1}\right\rangle$ such that $\forall \alpha<\omega_{1} \forall n \in \omega\left[f_{\alpha}(n)<f_{\alpha}(n+1)\right]$. For each $\alpha \geq 1$, define $e_{\alpha}$ and $g_{\alpha}$ by induction on $\alpha$ as follows. If $\alpha$ is a successor, then $e_{\alpha}: \omega \rightarrow \alpha$ is any onto function, and $g_{\alpha}=f_{\alpha}$. If $\alpha$ is a limit, then let $\left\{e_{n}: n \in \omega\right\}$ enumerate $\left\{e_{\xi}: \xi<\alpha\right\}$. Now, define $e_{\alpha}: \omega \rightarrow \alpha$ and $g_{\alpha} \in \omega^{\omega}$ such that
(3) $\forall n \in \omega\left[g_{\alpha}(n) \leq g_{\alpha}(n+1)\right]$
(4) $\forall n \in \omega \forall i \leq n \forall j \leq f_{\alpha}(n) \exists k<g_{\alpha}(n)\left[e_{\alpha}(k)=e_{i}(j)\right]$.

Observe that such an $e_{\alpha}$ must be a surjection. For each $n \in \omega$, put $w_{\alpha}(n)=\left\{e_{\alpha}(i)\right.$ : $\left.i \leq g_{\alpha}(n)\right\}$.

Now fix $\alpha<\omega_{1}$ and assume that $T_{\epsilon} \subset \omega^{<\omega}$ has been defined for each $\epsilon<\alpha$ such that each $T_{\epsilon}$ is finitely branching and $\bigcup_{\epsilon<\alpha}\left[T_{\epsilon}\right]$ is an a.d. family in $\omega^{\omega}$. Let $\left\langle\epsilon_{n}: n \in \omega\right\rangle$ enumerate $\alpha$, possibly with repetitions. For a tree $T \subset \omega^{<\omega}$ and $l \in \omega$, $T \upharpoonright l$ denotes $\{\sigma \in T:|\sigma| \leq l\}$, and $T(l)$ denotes $\{\sigma \in T:|\sigma|=l\}$. We will define a sequence of natural numbers $0=l_{0}<l_{1}<\cdots$ and determine $T_{\alpha} \upharpoonright l_{n}$ by induction on $n$. $T_{\alpha} \upharpoonright l_{0}=\{0\}$. Assume that $l_{n}$ and $T_{\alpha} \upharpoonright l_{n}$ are given. Suppose also that we are given a sequence of natural numbers $\left\langle k_{i}: i<n\right\rangle$ such that
(5) $\forall i<i+1<n\left[k_{i}<k_{i+1}\right]$
(6) $I_{k_{i}}^{\alpha} \subset\left[0, l_{n}\right)$.

Let $\sigma^{*}$ denote the member of $T_{\alpha}\left(l_{n}\right)$ that is right most with respect to the lexicographical ordering on $\omega^{l_{n}}$. Suppose we are also given $L_{n}: T_{\alpha}\left(l_{n}\right) \backslash\left\{\sigma^{*}\right\} \rightarrow W_{n}$, an injection. Here $W_{n}$ is the set of all pairs $\left\langle p_{0}, \bar{h}\right\rangle$ such that
(7) there are $s \in[\omega]^{<\omega}$, and numbers $i_{0}<j_{0} \leq n$ such that
(a) $s \subset \bigcup_{i \in\left[i_{0}, j_{0}\right)} I_{k_{i}}^{\alpha}$
(b) for each $i \in\left[i_{0}, j_{0}\right),\left|s \cap I_{k_{i}}^{\alpha}\right|=1$
(c) $p_{0}: s \rightarrow \omega$ such that $\forall m \in s\left[p_{0}(m) \leq f_{\alpha}(m)\right]$
(8) There is $j_{1}<n$ such that $\bar{h}=\left\langle h_{\epsilon_{i}}: i \leq j_{1}\right\rangle$ (if $\alpha=0$, this means that $\bar{h}=0)$. For each $i \leq j_{1}, h_{\epsilon_{i}}: T_{\epsilon_{i}} \upharpoonright \max (s)+1 \rightarrow w_{\alpha}(\max (s)+1)$ such that $\left(*_{1}\right)$ and $\left(*_{2}\right)$ hold when $T$ is replaced there with $T_{\epsilon_{i}} \upharpoonright \max (s)+1, H_{T, p}$ is replaced with $h_{\epsilon_{i}}, A$ with $s$, and $p$ with $p_{0}$.
Assume that for each $i<n$, we are also given $\sigma_{i} \in T_{\alpha}\left(l_{i}\right)$, which we will call the active node at stage $i$. Note that $T_{\alpha}\left(l_{0}\right)=\{0\}$, and so $\sigma_{0}=0$. For each $\sigma \in T_{\alpha}\left(l_{n}\right)$, let $\Delta(\sigma)=\max \left(\{0\} \cup\left\{i<n: \sigma_{i}=\sigma \upharpoonright l_{i}\right\}\right)$. For, $\sigma, \tau \in T_{\alpha}\left(l_{n}\right)$, say $\sigma \triangleleft \tau$ if either $\Delta(\sigma)<\Delta(\tau)$ or $\Delta(\sigma)=\Delta(\tau)$ and $\sigma$ is to the left of $\tau$ in the lexicographic ordering on $\omega^{l_{n}}$. Let $\sigma_{n}$ be the $\triangleleft$-minimal member of $T_{\alpha}\left(l_{n}\right) . \sigma_{n}$ will be active at stage $n$. The meaning of this is that none of the other nodes in $T_{\alpha}\left(l_{n}\right)$ will be allowed to branch at stage $n$. Choose $k_{n}$ greater than all $k_{i}$ for $i<n$ such that $I_{k_{n}}^{\alpha} \subset\left[l_{n}, \infty\right)$. Let $V_{n}$ be the set of all pairs $\left\langle p_{1}, \overline{\mathbf{h}}\right\rangle$ such that
(9) there exist $s$ and a natural number $i_{1} \leq n$ such that
(a) $s \subset \bigcup_{i \in\left[i_{1}, n+1\right)} I_{k_{i}}^{\alpha}$
(b) for each $i \in\left[i_{1}, n+1\right),\left|s \cap I_{k_{i}}^{\alpha}\right|=1$
(c) $p_{1}: s \rightarrow \omega$ such that $\forall m \in s\left[p_{1}(m) \leq f_{\alpha}(m)\right]$
(10) There is $j_{2} \leq n$ such that $\overline{\mathbf{h}}=\left\langle\mathbf{h}_{\epsilon_{i}}: i \leq j_{2}\right\rangle$. For each $i \leq j_{2}, \mathbf{h}_{\epsilon_{i}}: T_{\epsilon_{i}} \upharpoonright$ $\max (s)+1 \rightarrow w_{\alpha}(\max (s)+1)$ such that $\left(*_{1}\right)$ and $\left(*_{2}\right)$ are satisfied when $T$ is replaced with $T_{\epsilon_{i}} \upharpoonright \max (s)+1, H_{T, p}$ is replaced with $\mathbf{h}_{\epsilon_{i}}, A$ with $s$, and $p$ with $p_{1}$.
Note that $V_{n}$ is always finite. Now, the construction splits into two cases.
Case I: $\sigma_{n} \neq \sigma^{*}$. Put $\left\langle p_{0}, \bar{h}\right\rangle=L_{n}\left(\sigma_{n}\right)$. Let $i_{0}<n$ be as in (7) above, and let $j_{1}<n$ be as in (8). Let

$$
U_{n}=\left\{\left\langle p_{1}, \overline{\mathbf{h}}\right\rangle \in V_{n}: p_{0} \subset p_{1} \wedge i_{0}=i_{1} \wedge j_{1}<j_{2} \wedge \forall i \leq j_{1}\left[\mathbf{h}_{\epsilon_{i}} \upharpoonright \operatorname{dom}\left(h_{\epsilon_{i}}\right)=h_{\epsilon_{i}}\right]\right\}
$$

Here $i_{1}$ is as in (9), and $j_{2}$ is as in (10) with respect to $\left\langle p_{1}, \overline{\mathbf{h}}\right\rangle$. Now choose $l_{n+1}>l_{n}$ large enough so that $I_{k_{n}}^{\alpha} \subset\left[l_{n}, l_{n+1}\right)$ and so that it is possible to pick $\left\{\tau_{x}: x \in U_{n}\right\} \subset \omega^{l_{n+1}}$ and $\left\{\tau_{\sigma}: \sigma \in T_{\alpha}\left(l_{n}\right)\right\} \subset \omega^{l_{n+1}}$ such that the following conditions are satisfied.
(11) for each $x \in U_{n}, \tau_{x} \supset \sigma_{n}$, and for each $\sigma \in T_{\alpha}\left(l_{n}\right), \tau_{\sigma} \supset \sigma$
(12) for each $x, y \in U_{n}$, if $x \neq y$, then there exists $m \in\left[l_{n}, l_{n+1}\right)$ such that $\tau_{x}(m) \neq \tau_{y}(m)$. For each $x \in U_{n}$, there exists $m \in\left[l_{n}, l_{n+1}\right)$ such that $\tau_{x}(m) \neq \tau_{\sigma_{n}}(m)$. For $x=\left\langle p_{1}, \overline{\mathbf{h}}\right\rangle \in U_{n}$, if $\left\{i^{*}\right\}=\operatorname{dom}\left(p_{1}\right) \cap I_{k_{n}}^{\alpha}$, then $p_{1}\left(i^{*}\right)=\tau_{x}\left(i^{*}\right)$.
(13) for each $x \in U_{n}$ and $\sigma \in T_{\alpha}\left(l_{n}\right), \forall m \in\left[l_{n}, l_{n+1}\right)\left[\tau_{x}(m) \neq \tau_{\sigma}(m)\right]$. For $\sigma, \eta \in T_{\alpha}\left(l_{n}\right)$, if $\sigma \neq \eta$, then $\forall m \in\left[l_{n}, l_{n+1}\right)\left[\tau_{\sigma}(m) \neq \tau_{\eta}(m)\right]$.
(14) for each $i \leq n, \tau \in T_{\epsilon_{i}}\left(l_{n+1}\right), \sigma \in T_{\alpha}\left(l_{n}\right)$ and $m \in\left[l_{n}, l_{n+1}\right), \tau(m) \neq \tau_{\sigma}(m)$. For each $x \in U_{n}, i \leq j_{2}, \tau \in T_{\epsilon_{i}}\left(l_{n+1}\right)$ and $m \in\left[l_{n}, l_{n+1}\right)$, if $\tau_{x}(m)=\tau(m)$, then $m \in \operatorname{dom}\left(p_{1}\right)$ and $p_{1}(m)=\tau_{x}(m)$.
Define $L_{n+1}$ as follows. For any $x \in U_{n}, L_{n+1}\left(\tau_{x}\right)=x$. For any $\sigma \in T_{\alpha}\left(l_{n}\right) \backslash\left\{\sigma^{*}\right\}$, $L_{n+1}\left(\tau_{\sigma}\right)=L_{n}(\sigma)$. This finishes case I.

Case II: $\sigma_{n}=\sigma^{*}$. For each $\sigma \in T_{\alpha}\left(l_{n}\right) \backslash\left\{\sigma_{n}\right\}$, let $\left\langle p_{0}(\sigma), \bar{h}(\sigma)\right\rangle=L_{n}(\sigma)$. Let $i_{0}(\sigma)<n$ witness (7) for $L_{n}(\sigma)$ and let $j_{1}(\sigma)<n$ witness (8) for $L_{n}(\sigma)$. Let $U_{n}$ be the set of all $\left\langle p_{1}, \overline{\mathbf{h}}\right\rangle \in V_{n}$ such that there is no $\sigma \in T_{\alpha}\left(l_{n}\right) \backslash\left\{\sigma_{n}\right\}$ so that

$$
p_{0}(\sigma) \subset p_{1} \wedge i_{0}(\sigma)=i_{1} \wedge j_{1}(\sigma)<j_{2} \wedge \forall i \leq j_{1}(\sigma)\left[\mathbf{h}_{\epsilon_{i}} \upharpoonright \operatorname{dom}\left(h_{\epsilon_{i}}\right)=h_{\epsilon_{i}}\right]
$$

Here $i_{1} \leq n$ and $j_{2} \leq n$ witness (9) and (10) respectively with respect to $\left\langle p_{1}, \overline{\mathbf{h}}\right\rangle$. Choose $l_{n+1}>l_{n}$ large enough so that $I_{k_{n}}^{\alpha} \subset\left[l_{n}, l_{n+1}\right)$ and so that it is possible to choose $\left\{\tau^{*}\right\},\left\{\tau_{x}: x \in U_{n}\right\}$, and $\left\{\tau_{\sigma}: \sigma \in T_{\alpha}\left(l_{n}\right) \backslash\left\{\sigma_{n}\right\}\right\}$, subsets of $\omega^{l_{n+1}}$, satisfying the following conditions.
(15) $\tau^{*} \supset \sigma_{n}$. For each $x \in U_{n}, \tau_{x} \supset \sigma_{n}$. For each $\sigma \in T_{\alpha}\left(l_{n}\right) \backslash\left\{\sigma_{n}\right\}, \tau_{\sigma} \supset \sigma$.
(16) $\tau^{*}$ is the right most branch of $T_{\alpha}\left(l_{n+1}\right)$. For each $x \in U_{n}$, there exists $m \in\left[l_{n}, l_{n+1}\right)$ such that $\tau^{*}(m) \neq \tau_{x}(m)$. For each $x, y \in U_{n}$, if $x \neq y$, then there is $m \in\left[l_{n}, l_{n+1}\right)$ so that $\tau_{x}(m) \neq \tau_{y}(m)$. For each $x=\left\langle p_{1}, \overline{\mathbf{h}}\right\rangle \in U_{n}$, if $\left\{i^{*}\right\}=I_{k_{n}}^{\alpha} \cap \operatorname{dom}\left(p_{1}\right)$, then $p_{1}\left(i^{*}\right)=\tau_{x}\left(i^{*}\right)$.
(17) For each $x \in U_{n}$ and $m \in\left[l_{n}, l_{n+1}\right), \tau_{x}(m) \neq \tau^{*}(m)$. For each $\sigma \in T_{\alpha}\left(l_{n}\right) \backslash$ $\left\{\sigma_{n}\right\}$ and for each $m \in\left[l_{n}, l_{n+1}\right), \tau^{*}(m) \neq \tau_{\sigma}(m)$, and for each $x \in U_{n}$, $\tau_{\sigma}(m) \neq \tau_{x}(m)$. For each $\sigma, \eta \in T_{\alpha}\left(l_{n}\right) \backslash\left\{\sigma_{n}\right\}$, if $\sigma \neq \eta$, then for all $m \in\left[l_{n}, l_{n+1}\right), \tau_{\sigma}(m) \neq \tau_{\eta}(m)$.
(18) For each $i \leq n, \tau \in T_{\epsilon_{i}}\left(l_{n+1}\right), m \in\left[l_{n}, l_{n+1}\right)$, and $\sigma \in T_{\alpha}\left(l_{n}\right) \backslash\left\{\sigma_{n}\right\}$, $\tau^{*}(m) \neq \tau(m)$ and $\tau_{\sigma}(m) \neq \tau(m)$. For each $x=\left\langle p_{1}, \mathbf{h}\right\rangle \in U_{n}, i \leq j_{2}$, $\tau \in \tau_{\epsilon_{i}}\left(l_{n+1}\right)$ and $m \in\left[l_{n}, l_{n+1}\right)$, if $\tau_{x}(m)=\tau(m)$, then $m \in \operatorname{dom}\left(p_{1}\right)$ and $p_{1}(m)=\tau_{x}(m)$.
For each $\sigma \in T_{\alpha}\left(l_{n}\right) \backslash\left\{\sigma_{n}\right\}$, define $L_{n+1}\left(\tau_{\sigma}\right)=L_{n}(\sigma)$. For each $x \in U_{n}$, set $L_{n+1}\left(\tau_{x}\right)=x$. This completes the construction. We now check that it is as required.
Lemma 6. For each $f \in\left[T_{\alpha}\right]$, there are infinitely many $n \in \omega$ such that $\sigma_{n}=f \upharpoonright l_{n}$.
Proof. For each $n \in \omega$ put $\Theta(n)=\min \left\{\Delta(\sigma): \sigma \in T_{\alpha}\left(l_{n}\right)\right\}$. It is clear from the construction that $\Theta(n+1) \geq \Theta(n)$. If the lemma fails, then there are $m$ and $\tau \in T_{\alpha}\left(l_{m+1}\right)$ with the property that for infinitely many $n>m+1$, there is a $\sigma \in T_{\alpha}\left(l_{n}\right)$ such that $\Theta(n)=\Delta(\sigma)=m$ and $\sigma \upharpoonright l_{m+1}=\tau$. Let $\tau$ be the left most node in $T_{\alpha}\left(l_{m+1}\right)$ with this property. Choose $n_{1}>n_{0}>m+1$ and $\sigma \in T_{\alpha}\left(l_{n_{1}}\right)$ such that $\Theta\left(n_{1}\right)=\Theta\left(n_{0}\right)=\Delta(\sigma)=m, \sigma \upharpoonright l_{m+1}=\tau$, and there is no $\eta \in T_{\alpha}\left(l_{n_{0}}\right)$ such that $\Delta(\eta)=m$ and $\eta \upharpoonright l_{m+1}$ is to the left of $\tau$. Note that $\Delta\left(\sigma \upharpoonright l_{n_{0}}\right)=m$. So $\sigma_{n_{0}}$ is to the left of $\sigma \upharpoonright l_{n_{0}}$, and $\sigma_{n_{0}} \upharpoonright l_{m+1}$ is not to the left of $\tau$, whence $\sigma_{n_{0}} \upharpoonright l_{m+1}=\tau$. But then there is some $n \in\left[m+1, n_{0}\right)$ where $\sigma \upharpoonright l_{n}$ was active, a contradiction. $\dashv$

Note that Lemma 6 implies that for any $\sigma \in T_{\alpha}$, there is a unique minimal extension of $\sigma$ which is active. Lemma 6 also implies that there are infinitely many $n$ where case II occurs.

Lemma 7. $T_{\alpha}$ is finitely branching and $\bigcup_{\epsilon \leq \alpha}\left[T_{\epsilon}\right]$ is a.d. in $\omega^{\omega}$.
Proof. It is clear from the construction that $T_{\alpha}$ is finitely branching. Fix $f, g \in\left[T_{\alpha}\right]$, with $f \neq g$. Let $n=\max \left\{i \in \omega: f \upharpoonright l_{i}=g \upharpoonright l_{i}\right\}$. It is clear from the construction that $\forall m \geq l_{n+1}[f(m) \neq g(m)]$.

Next, fix $\epsilon<\alpha$. Suppose $\epsilon=\epsilon_{i}$. Let $h \in\left[T_{\epsilon_{i}}\right]$ and $f \in\left[T_{\alpha}\right]$, and suppose for a contradiction that $|h \cap f|=\aleph_{0}$. So there are infinitely many $n \in \omega$ such that $f \upharpoonright\left[l_{n}, l_{n+1}\right) \cap h \upharpoonright\left[l_{n}, l_{n+1}\right) \neq 0$. For any $n \geq i$, this can only happen if $f \upharpoonright l_{n}=\sigma_{n}$ and $f \upharpoonright l_{n+1}=\tau_{x_{n}}$ for some $x_{n} \in U_{n}$. This is because if $n \geq i$ and $f \upharpoonright\left[l_{n}, l_{n+1}\right) \cap h \upharpoonright\left[l_{n}, l_{n+1}\right) \neq 0$, then when case I occurs, (14) says that $f \upharpoonright l_{n+1} \neq \tau_{\sigma}$ for any $\sigma \in T_{\alpha}\left(l_{n}\right)$, while when case II occurs, by (18), $f \upharpoonright l_{n+1} \neq \tau^{*}$ and also $f \upharpoonright l_{n+1} \neq \tau_{\sigma}$ for any $\sigma \in T_{\alpha}\left(l_{n}\right) \backslash\left\{\sigma_{n}\right\}$. So $f \upharpoonright l_{n+1}=\tau_{x_{n}}$ for some $x_{n} \in U_{n}$, and $f \upharpoonright l_{n}=\sigma_{n}$. Now, put $x_{n}=\left\langle p_{1, n}, \overline{\mathbf{h}}_{n}\right\rangle$. Note that in this case $L_{n+1}\left(f \upharpoonright l_{n+1}\right)=x_{n}$. For such $n$, let $j_{2}(n)$ be as in (10) with respect to $x_{n}$. So for infinitely many such $n, j_{2}(n) \geq i$. But then for infinitely many such $n, \mathbf{h}_{\epsilon_{i}, n}(h \upharpoonright$ $\left.\max \left(\operatorname{dom}\left(p_{1, n}\right)\right)+1\right)<\mathbf{h}_{\epsilon_{i}, n}\left(h \upharpoonright l_{n}\right)$, producing an infinite strictly descending sequence of ordinals.

Lemma 8. For each $A \in[\omega]^{\omega}$ and $p: A \rightarrow \omega$, there are $\alpha<\omega_{1}$ and $f \in\left[T_{\alpha}\right]$ such that $|p \cap f|=\aleph_{0}$.

Proof. Suppose for a contradiction that there are $A \in[\omega]^{\omega}$ and $p: A \rightarrow \omega$ such that $p$ is a.d. from $\left[T_{\alpha}\right]$, for each $\alpha<\omega_{1}$. Let $M \prec H(\theta)$ be a countable elementary submodel containing everything relevant. Put $\alpha=M \cap \omega_{1}$. For each $\epsilon<\alpha$, let $H_{\epsilon}$ denote $H_{T_{\epsilon}, p}$, and note that $H_{\epsilon}$ and $\operatorname{ran}\left(H_{\epsilon}\right)$ are members of $M$. Let $\xi_{\epsilon}=$ $\sup \left(\operatorname{ran}\left(H_{\epsilon}\right)\right)+1<\alpha$. Find $g \in M \cap \omega^{\omega}$ such that for $n \in \omega, H_{\epsilon}^{\prime \prime} T_{\epsilon} \upharpoonright n \subset\left\{e_{\xi_{\epsilon}}(j)\right.$ : $j \leq g(n)\}$. Since $\forall^{\infty} n \in \omega\left[g(n) \leq f_{\alpha}(n)\right]$, it follows from (4) that for all but finitely many $n \in \omega$, for all $\sigma \in T_{\epsilon} \upharpoonright n, H_{\epsilon}(\sigma) \in w_{\alpha}(n)$. Now, find an infinite $q \subset p$ such that $\forall m \in \operatorname{dom}(q)\left[q(m) \leq f_{\alpha}(m)\right]$ and $\forall^{\infty} n \in \omega\left[\left|\operatorname{dom}(q) \cap I_{n}^{\alpha}\right|=1\right]$.

Note that for any $\epsilon<\alpha,\left(*_{1}\right)$ and $\left(*_{2}\right)$ are satisfied when $T$ is replaced there with $T_{\epsilon}, H_{T, p}$ is replaced with $H_{\epsilon}, A$ with $\operatorname{dom}(q)$, and $p$ with $q$. But now, it follows from the construction that there is $f \in\left[T_{\alpha}\right]$ such that for infinitely many $n \in \omega$, there is $m \in\left[l_{n}, l_{n+1}\right) \cap \operatorname{dom}(q)$ such that $q(m)=f(m)$. We describe how to find such a $f \in\left[T_{\alpha}\right] . \forall^{\infty} n \in \omega\left[\left|\operatorname{dom}(q) \cap I_{k_{n}}^{\alpha}\right|=1\right]$. For each $n \in \omega$ such that $\left|\operatorname{dom}(q) \cap I_{k_{n}}^{\alpha}\right|=1$, let $m_{n}$ be the unique member of $\operatorname{dom}(q) \cap I_{k_{n}}^{\alpha}$. We observed above that for any $\epsilon<\alpha$, for all but finitely many $n \in \omega$, for each $\sigma \in T_{\epsilon} \upharpoonright n$, $H_{\epsilon}(\sigma) \in w_{\alpha}(n)$. It follows that for any $i \in \omega$, there is $u_{i} \geq i$ such that for each $j \leq i$ and each $n \geq u_{i}, m_{n}$ is defined and $\forall \sigma \in T_{\epsilon_{j}} \upharpoonright m_{n}+1\left[H_{\epsilon_{j}}(\sigma) \in w_{\alpha}\left(m_{n}+1\right)\right]$. Choose $n^{*} \geq u_{0}$ so that case II occurs at stage $n^{*}$. Put $\eta_{0}=\sigma_{n^{*}}$. Define $s_{0}=\left\{m_{n^{*}}\right\}$ and $q_{0}=q \upharpoonright s_{0}$. Put $\bar{h}_{0}=\left\langle h_{0}\right\rangle$, where $h_{0}=H_{\epsilon_{0}} \upharpoonright\left(T_{\epsilon_{0}} \upharpoonright \max \left(s_{0}\right)+1\right)$. Note that $h_{0}$ is a map from $T_{\epsilon_{0}} \upharpoonright \max \left(s_{0}\right)+1$ to $w_{\alpha}\left(\max \left(s_{0}\right)+1\right)$, and so $x_{0}=\left\langle q_{0}, \bar{h}_{0}\right\rangle \in V_{n^{*}}$. Since $m_{n^{*}} \notin I_{k_{i}}^{\alpha}$ for any $i<n^{*}$, it follows that $x_{0} \in U_{n^{*}}$. Put $\eta_{1}=\tau_{x_{0}} \supsetneq \eta_{0}$. Notice that $\eta_{1}\left(m_{n^{*}}\right)=q\left(m_{n^{*}}\right)$. Notice also that $\eta_{1}$ is not the right most branch of $T_{\alpha}\left(l_{\left(n^{*}+1\right)}\right)$, and so if $\sigma$ is any extension of $\eta_{1}$ that happens to be active at a certain stage, then case I necessarily occurs at that stage. Finally, note that $L_{n^{*}+1}\left(\eta_{1}\right)=x_{0}$. Now, for each $n>n^{*}$, let $s_{n}=\left\{m_{j}: n^{*} \leq j \leq n\right\}$, and put $q_{n}=q \upharpoonright s_{n}$. For any $i>0$ and $n>n^{*}$, if $n \geq u_{i}$, then for each $j \leq i$, define $h_{j}^{n}=H_{\epsilon_{j}} \upharpoonright\left(T_{\epsilon_{j}} \upharpoonright \max \left(s_{n}\right)+1\right)$. Put $\bar{h}_{i}^{n}=\left\langle h_{j}^{n}: j \leq i\right\rangle$ and $x_{i}^{n}=\left\langle q_{n}, \bar{h}_{i}^{n}\right\rangle$. Note that for any $i>0$ and $n>n^{*}$, if $n \geq u_{i}$, then $x_{i}^{n} \in V_{n}$. Moreover, if at stage $n$, case I occurs and $L_{n}\left(\sigma_{n}\right)=x_{i-1}^{v}$ for some $v \in \omega$, then $x_{i}^{n} \in U_{n}$; here $x_{0}^{v}=x_{0}$, for all $v \in \omega$. Now, it is easy to see that there is a branch $g \in\left[T_{\alpha}\right]$ such that $\eta_{1} \subset g$ and $\forall n \geq n^{*}+1\left[L_{n}\left(g \upharpoonright l_{n}\right)=x_{0}\right]$. This is because for any $n \geq n^{*}+1$, given $g \upharpoonright l_{n}$ such that $\eta_{1} \subset g \upharpoonright l_{n}$ and $L_{n}\left(g \upharpoonright l_{n}\right)=x_{0}$, if $\sigma$ is the unique minimal extension of $g \upharpoonright l_{n}$ that is active, then $\tau_{\sigma} \supsetneq g \upharpoonright l_{n}$ and $L_{u+1}\left(\tau_{\sigma}\right)=x_{0}$, where $u$ is the stage at which $\sigma$ is active. Applying Lemma 6 to $g$, find $n^{* *}$ such that $n^{* *}>n^{*}, n^{* *} \geq u_{1}$, and $\sigma_{n^{* *}}=g \upharpoonright l_{n^{* *}}$. It follows that $x_{1}^{n^{* *}} \in U_{n^{* *}}$. Let $\eta_{2}=\tau_{x_{1}^{n * *}} \supsetneq \eta_{1}$. Note that $\eta_{2}\left(m_{n^{* *}}\right)=q\left(m_{n^{* *}}\right)$ and that $L_{n^{* *}+1}\left(\eta_{2}\right)=x_{1}^{n^{* *}}$. Continuing in this fashion, we get $f=\bigcup_{n \in \omega} \eta_{n} \in\left[T_{\alpha}\right]$ with $|f \cap q|=\omega$.

## 3. Remarks and Questions

The construction in this paper is very specific to $\omega_{1}$; indeed, it is possible to show that $\mathfrak{d}$ is not always an upper bound for $\mathfrak{a}_{\text {closed }}$. A modification of the methods of Section 4 of [4] shows that if $\kappa$ is a measurable cardinal and if $\lambda=\operatorname{cf}(\lambda)=\lambda^{\kappa}>$ $\mu=\operatorname{cf}(\mu)>\kappa$, then there is a c.c.c. poset $\mathbb{P}$ such that $|\mathbb{P}|=\lambda$, and $\mathbb{P}$ forces that $\mathfrak{b}=\mathfrak{d}=\mu$ and $\mathfrak{a}=\mathfrak{a}_{\text {closed }}=\mathfrak{c}=\lambda$.

As mentioned in Section 1, we see the result in this paper as providing a weak positive answer to the following basic question, which has remained open for long.

Question 9. If $\mathfrak{d}=\aleph_{1}$, then is $\mathfrak{a}=\aleph_{1}$ ?
There are also several open questions about upper and lower bounds for $\mathfrak{a}_{\text {closed }}$.
Question 10 (Brendle and Khomskii [1]). If $\mathfrak{s}=\aleph_{1}$, then is $\mathfrak{a}_{\text {closed }}=\aleph_{1}$ ?
Question 11. Is $\mathfrak{h} \leq \mathfrak{a}_{\text {closed }}$ ?
Regarding Question 10, it is proved in Brendle and Khomskii [1] that if $\mathbf{V}$ is any ground model satisfying CH , then any finite support iteration of Suslin c.c.c. posets in $\mathbf{V}$ forces that $\mathfrak{a}_{\text {closed }}=\aleph_{1}$. It is well known that $\mathbf{V}$ remains a splitting
family after such a finite support iteration of Suslin c.c.c. posets. Showing a positive answer to Question 10 would be an improvement of the result in this paper.
