#### Abstract

We investigate the existence of strong colorings on successors of singular cardinals. This work continues Section 2 of [1], but now our emphasis is on finding colorings of pairs of ordinals, rather than colorings of finite sets of ordinals.

## 1. Introduction

The theme of this paper is that strong coloring theorems hold at successors of singular cardinals of uncountable cofinality, except possibly in the case where the singular cardinal is a limit of regular cardinals that are Jonsson in a strong sense.

Our general framework is that $\lambda=\mu^{+}$, where $\mu$ is singular of uncountable cofinality. We will be searching for colorings of pairs of ordinals $<\lambda$ that exhibit quite complicated behaviour. The following definition (taken from [2]) explains what "complicated" means in the previous sentence.

Definition 1.1. Let $\lambda$ be an infinite cardinal, and suppose $\kappa+\theta \leq \mu \leq \lambda$. $\operatorname{Pr}_{1}(\lambda, \mu, \kappa, \theta)$ means that there is a symmetric two-place function $c$ from $\lambda$ to $\kappa$ such that if $\xi<\theta$ and for $i<\mu,\left\langle\alpha_{i, \zeta}: \zeta<\xi\right\rangle$ is a strictly increasing sequence of ordinals $<\lambda$ with all $\alpha_{i, \zeta}$ 's distinct, then for every $\gamma<\kappa$ there are $i<j<\mu$ such that

$$
\begin{equation*}
\zeta_{1}<\xi \text { and } \zeta_{2}<\xi \Longrightarrow c\left(\alpha_{i, \zeta_{1}}, \alpha_{i, \zeta_{2}}\right)=\gamma . \tag{1.1}
\end{equation*}
$$

Just as in [1], one of our main tools is a game that measures how "Jonsson" a given cardinal is.

Recall that a cardinal $\lambda$ is a Jonsson cardinal if for every $c:[\lambda]^{<\omega} \rightarrow \lambda$, we can find a subset $I \subseteq \lambda$ of cardinality $\lambda$ such that the range of $c \upharpoonright I$ is a proper subset of $\lambda$. A reader seeking more background should investigate [4] and [3] in [5].

[^0]Definition 1.2. Assume $\mu \leq \lambda$ are cardinals, $\gamma$ is an ordinal, $n \leq \omega$, and $J$ is an ideal on $\lambda$. We define the game $\mathrm{Gm}_{J}^{n}[\lambda, \mu, \gamma]$ as follows:

A play lasts $\gamma$ moves.
In the $\alpha^{\text {th }}$ move, the first player chooses a function $F_{\alpha}:[\lambda]^{<n} \rightarrow \mu$, and the second player responds by choosing (if possible) a subset $A_{\alpha} \subseteq \lambda$ such that

- $A_{\alpha} \subseteq \bigcap_{\beta<\alpha} A_{\beta}$
- $A_{\alpha} \in J^{+}$
- $\operatorname{ran}\left(F_{\alpha} \upharpoonright\left[A_{\alpha}\right]^{<n}\right)$ is a proper subset of $\mu$.

The second player loses if he has no legal move for some $\alpha<\gamma$, and he wins otherwise.

In the previous definition, if $J=J_{\lambda}^{\text {bd }}$ then we may omit it. Note that it causes no harm if we use a set $E$ of cardinality $\lambda$ instead of $\lambda$ itself; in this case, we write $\mathrm{Gm}_{J}^{n}[E, \mu, \gamma]$.

Note that $\lambda$ is a Jonsson cardinal if and only if Player I does not have a winning strategy in the game $\operatorname{Gm}^{\omega}[\lambda, \lambda, 1]$. One may view the lack of a winning strategy for Player I in games of longer length as a strong version of Jonsson-ness or a weak version of measurability - if $\lambda$ is measurable, then Player II can make sure her moves are elements of some $\lambda$-complete ultrafilter.

The following claim investigates how the existence of winning strategies is affected by modifications to the game; the proof is left to the reader.

Claim 1.3.
(1) If $\mu^{\prime} \leq \mu$ and the first player has a winning strategy in $\operatorname{Gm}_{J}^{n}[\lambda, \mu, \gamma]$, then she has a winning strategy in $\operatorname{Gm}_{J}^{n}\left[\lambda, \mu^{\prime}, \gamma\right]$.
(2) Suppose we weaken the demand on the second player to

$$
\begin{equation*}
\text { " }(\exists \zeta<\lambda)\left[\operatorname{ran}\left(F_{\alpha} \upharpoonright\left[A_{\alpha} \backslash \zeta\right]^{<n}\right) \text { is a proper subset of } \mu\right] \text {." } \tag{1.2}
\end{equation*}
$$

If $\mathrm{cf}(\lambda) \geq \gamma$ and $J \supseteq J_{\lambda}^{\text {bd }}$, then the first player has a winning strategy in the revised game if and only if she has a winning strategy in the original game.
(3) If $J$ is $\gamma$-complete, then the same applies to the case where we weaken the demand on the second player to

$$
\begin{equation*}
"(\exists Y \in J)\left[\operatorname{ran}\left(F_{\alpha} \backslash\left[A_{\alpha} \backslash Y\right]^{<n}\right) \text { is a proper subset of } \mu\right] . " \tag{1.3}
\end{equation*}
$$

(4) We can allow the second player to pass, i.e., to let $A_{\alpha}=\bigcap_{\beta<\alpha} A_{\beta}$ (even if this is not a legal move) as long as we declare that the second player loses if the order-type of the set of moves where he did not pass is $<\gamma$.
(5) If Player I has a winning strategy in $\mathrm{Gm}_{J}^{n}[\lambda, \mu, \gamma]$ for every $\mu<\mu^{*}$ where $\mu^{*}$ is singular and $\gamma>\operatorname{cf}\left(\mu^{*}\right)$ is regular, then Player I has a winning strategy in $\operatorname{Gm}_{J}^{n}\left[\lambda, \mu^{*}, \gamma\right]$. We can weaken the requirement that $\gamma$ is regular and instead require that $\operatorname{cf}(\gamma)>\operatorname{cf}\left(\mu^{*}\right)$ and $\omega^{\gamma}=\gamma$.

In Section 2 of [1], the existence of winning strategies for Player I in variants of the game is investigated. We will prove one such result here; the reader should look in [1] for others.

Claim 1.4. If $2^{\chi}<\lambda<\beth_{\left(2^{x}\right)^{+}}(\chi)$ then Player I has a winning strategy in $\operatorname{Gm}^{\omega}\left[\lambda, \chi,\left(2^{\chi}\right)^{+}\right]$.

Proof. At a stage $i$, Player I will select a function $F_{i}:[\lambda]^{<\omega} \rightarrow \chi$ coding the Skolem functions of some model $M_{i}$.

For the initial move, we let the model $M_{0}$ have universe $\lambda$, and include in our language all relations on $\lambda$ and all functions from $\lambda$ to $\lambda$ of any finite arity that are first order definable in the structure $\left\langle H\left(\lambda^{+}\right), \in,<_{\lambda^{+}}^{*}\right\rangle$ with the parameters $\chi$ and $\lambda$.

For subsequent moves, $M_{i}$ is an expansion of $M_{0}$ with universe $\lambda$ that has all relations on $\lambda$ and all functions from $\lambda$ to $\lambda$ of any finite arity that are first order definable in the structure $\left\langle H\left(\lambda^{+}\right), \in,<_{\lambda^{+}}^{*}\right\rangle$ from the parameters $\chi, \lambda, M_{0}$, and $\left\langle A_{j}: j<i\right\rangle$.

To obtain the function $F_{i}$, we let $\left\langle F_{n}^{i}: n<\omega\right\rangle$ list the Skolem functions of $M_{i}$ in such a way that $F_{n}^{i}$ has $m_{i}(n) \leq n$ places. Let $h: \omega \rightarrow \omega$ be such that for all $n$, $h(n) \leq n$ and $h^{-1}(\{n\})$ is infinite. We then define

$$
F_{i}(u)= \begin{cases}F_{h(|u|)}^{i}\left(\left\{\alpha \in u:|u \cap \alpha|<m_{i}(n)\right\}\right) & \text { if this is }<\chi  \tag{1.4}\\ 0 & \text { otherwise }\end{cases}
$$

The point of doing this is that whenever Player II chooses $A_{i}$, we know that $\operatorname{ran}\left(F_{i} \upharpoonright\left[A_{i}\right]^{<\omega}\right)$ will look like the result of intersecting an elementary submodel of $M_{i}$ with $\chi$; in particular, this range will be closed under the functions from $M_{i}$.

Note that $M_{0}$ (and all expansions of it) has definable Skolem functions and so for any $i$ and $A \subseteq \lambda$, the Skolem hull of $A$ in $M_{i}$ (denoted by $\mathrm{Sk}_{M_{i}}(A)$ ) is well-defined.

Let $\left\langle\left(F_{i}, A_{i}\right): i<\left(2^{\chi}\right)^{+}\right\rangle$be a play of the game in which Player I uses this strategy (with $M_{i}$ the model corresponding to $F_{i}$ ). For each $i$, define

$$
\begin{equation*}
\alpha_{i}=\min \left\{\alpha:\left|\operatorname{Sk}_{M_{0}}\left(A_{i}\right) \cap \beth_{\alpha}(\chi)\right|>\chi\right\} . \tag{1.5}
\end{equation*}
$$

By the choice of $M_{0}$ and $M_{i}$, clearly $\alpha(i)$ is a successor ordinal or a limit ordinal of cofinality $\chi^{+}$, and

$$
\begin{equation*}
\left|\operatorname{Sk}_{M_{0}}\left(A_{i}\right) \cap \beth_{\alpha_{i}}(\chi)\right| \leq 2^{\chi} . \tag{1.6}
\end{equation*}
$$

Since $A_{i} \subseteq A_{j}$ for $i>j$, we know the sequence $\left\langle\alpha_{i}: i<\left(2^{\chi}\right)^{+}\right\rangle$is nondecreasing. Furthermore, for each $i$ we know

$$
\begin{equation*}
\alpha_{i}<\min \left\{\beta: \lambda \leq \beth_{\beta}(\chi)\right\}<\left(2^{\chi}\right)^{+} . \tag{1.7}
\end{equation*}
$$

This means that the sequence $\left\langle\alpha_{i}: i<\left(2^{\chi}\right)^{+}\right\rangle$is eventually constant, say with value $\alpha^{*}$. Let $i^{*}$ be the least ordinal $<\left(2^{\chi}\right)^{+}$such that $\alpha_{i}=\alpha^{*}$ for $i \geq i^{*}$.

Proposition 1.5. If $i^{*} \leq i<\left(2^{\chi}\right)^{+}$, then $\mathrm{Sk}_{M_{0}}\left(A_{i+1}\right) \cap \beth_{\alpha^{*}}(\chi)$ is a proper subset of $\operatorname{Sk}_{M_{0}}\left(A_{i}\right) \cap \beth_{\alpha^{*}}(\chi)$.

Proof. Note that $i^{*}, \alpha^{*}$, and $\beth_{\alpha^{*}}(\chi)$ are all elements of $M_{i+1}$ as they are definable in $\left\langle H\left(\lambda^{+}\right), \in,<_{\lambda^{+}}\right\rangle$from the parameters $M_{0}$ and $\left\langle A_{j}: j \leq i\right\rangle$. Furthermore,

$$
\begin{equation*}
\gamma^{*}:=\min \left\{\gamma<\lambda:\left|\operatorname{Sk}_{M_{0}}\left(A_{i}\right) \cap \gamma\right|=\chi\right\} \tag{1.8}
\end{equation*}
$$

is also definable in $M_{i+1}$ (and $<\left(2^{\chi}\right)^{+}$). Thus the language of $M_{i+1}$ includes a bijection between $\mathrm{Sk}_{M_{0}}\left(A_{i}\right) \cap \gamma^{*}$ and $\chi$.

If Player I has not won the game at this stage, after Player I selects $A_{i+1}$ we will be able to find an ordinal $\beta<\chi$ such that $\beta \notin \operatorname{ran}\left(F_{i+1} \upharpoonright\left[A_{i+1}\right]^{<\omega}\right)$. By definition of $h$, we know $\beta^{\prime}:=h^{-1}(\beta)$ is an element of $\operatorname{Sk}_{M_{0}}\left(A_{i}\right) \cap \beth_{\alpha^{*}}(\chi)$. However, $\beta^{\prime}$ is not an element of $\mathrm{Sk}_{M_{i+1}}\left(A_{i+1}\right)$ - since $F_{i+1}$ codes the Skolem functions of $M_{i+1}$, the range of $F_{i+1} \upharpoonright\left[A_{i+1}\right]^{<\omega}$ is $\mathrm{Sk}_{M_{i+1}}\left(A_{i+1}\right) \cap \chi$. Since $\mathrm{Sk}_{M_{i+1}}\left(A_{i+1}\right)$ is closed under $h$, this contradicts our choice of $\beta$. Since $\mathrm{Sk}_{M_{0}}\left(A_{i+1}\right) \subseteq \operatorname{Sk}_{M_{i+1}}\left(A_{i+1}\right)$, we have established the proposition.

Note that the preceding proposition finishes the proof of the claim - if play of the game continues for all $\left(2^{\chi}\right)^{+}$steps, then $\left\langle\operatorname{Sk}_{M_{0}}\left(A_{i}\right) \cap \beth_{\alpha^{*}}(\chi): i<\left(2^{\chi}\right)^{+}\right\rangle$is a strictly decreasing family of subsets of $\mathrm{Sk}_{M_{0}}\left(A_{i^{*}}\right)$, contradicting (1.6).

## 2. Club-guessing technology

In this section, we prove that if $\lambda=\mu^{+}$, where $\mu$ is singular, then under certain circumstances we can find a complicated "library" of colorings of smaller cardinals. In the next section, we will use this library of colorings to get a complicated coloring of $\lambda$.

The basics of club-guessing are explained in [4], but we will take a few minutes to recall some of the definitions.

Let us recall that if $S$ is a stationary subset of $\lambda$, then an $S$-club system is a sequence $\bar{C}=\left\langle C_{\delta}: \delta \in S\right\rangle$ such that for (limit) $\delta \in S, C_{\delta}$ is closed unbounded in $\delta$.

In this section, we will be concerned with the case where $\lambda$ is the successor of a singular cardinal, i.e., $\lambda=\mu^{+}$where $\mathrm{cf}(\mu)<\mu$. In this context, if $\bar{C}$ is an $S$-club system, then for $\delta \in S$ we define an ideal $J_{\delta}^{b[\mu]}$ on $C_{\delta}$ by $A \in J_{\delta}^{b[\mu]}$ if and only if $A \subseteq C_{\delta}$, and for some $\theta<\mu$ and $\gamma<\delta$,

$$
\beta \in A \cap \operatorname{nacc}\left(C_{\delta}\right) \Rightarrow[\beta<\gamma \text { or } \operatorname{cf}(\beta)<\theta] .
$$

Note that it is a bit easier to understand the definition of $J_{\delta}^{b[\mu]}$ by looking at the contrapositive - a subset $A$ of $C_{\delta}$ is "large", i.e., not in $J_{\delta}^{b[\mu]}$, if and only if $A \cap \operatorname{nacc}\left(C_{\delta}\right)$ is cofinal in $\delta$, and the cofinalities of members of any end segment of $A \cap \operatorname{nacc}\left(C_{\delta}\right)$ are unbounded below $\mu$.
Claim 2.1. Let $\lambda=\mu^{+}$, where $\mu$ is a singular cardinal of cofinality $\kappa<\mu$. Let $S \subseteq \lambda$ be stationary, and assume that $\sup \{\operatorname{cf}(\delta): \delta \in S\}=\mu^{*}<\mu$. Let $\bar{C}$ be an $S$-club system, and for each $\delta \in S$, let $J_{\delta}$ be the ideal $J_{\delta}^{b[\mu]}$. Let $\left\langle\kappa_{i}: i<\kappa\right\rangle$ be a non-decreasing sequence of cardinals such that

$$
\begin{equation*}
\kappa^{*}=\sum_{i<\kappa} \kappa_{i} \leq \mu, \tag{2.1}
\end{equation*}
$$

and let $\gamma^{*}<\mu$.

Assume we are given a $\lambda$-club system $\bar{e}$ and a sequence of ideals $\bar{I}=\left\langle I_{\alpha}: \alpha<\right.$ $\lambda)$ such that
(1) $I_{\alpha}$ is an ideal on $e_{\alpha}$ extending $J_{e_{\alpha}}^{\mathrm{bd}}$
(2) if $\delta \in S$, then for each $i<\kappa$,

$$
\left\{\alpha \in \operatorname{nacc}\left(C_{\delta}\right): \text { Player I wins } \operatorname{Gm}_{I_{\alpha}}^{\omega}\left[e_{\alpha}, \kappa_{i}, \gamma^{*}\right]\right\}=\operatorname{nacc}\left(C_{\delta}\right) \bmod J_{\delta}
$$

(3) for any club $E \subseteq \lambda$, for stationarily many $\delta \in S$,

$$
\left\{\alpha \in \operatorname{nacc}\left(C_{\delta}\right): B_{0}\left[E, e_{\alpha}\right] \notin I_{\alpha}\right\} \notin J_{\delta},
$$

where

$$
B_{0}\left[E, e_{\alpha}^{*}\right]=\left\{\beta \in \operatorname{nacc}\left(e_{\alpha}\right): E \text { meets the interval }\left(\sup \left(\beta \cap e_{\alpha}\right), \beta\right)\right\} .
$$

Then there is a function $h: \lambda \rightarrow(\kappa+1)$ and a sequence

$$
\bar{F}=\left\langle F_{\delta}: \delta<\lambda, \delta \text { a limit }\right\rangle
$$

such that

$$
\circledast_{1} F_{\delta}:\left[e_{\delta}\right]^{<\omega} \longrightarrow \kappa_{h(\delta)}\left(\text { where } \kappa^{*}:=\kappa_{\kappa}\right)
$$

and
$\circledast_{2}$ for every club $E \subseteq \lambda$, for each $i<\kappa$ there are stationarily many $\delta \in S$ such that the set of $\beta \in \operatorname{nacc}\left(C_{\delta}\right)$ satisfying the following

- $h(\beta) \geq i$
- $B_{0}\left[E, e_{\beta}\right] \notin I_{\beta}$
- for all $\gamma<\beta, \kappa_{h(\beta)} \subseteq \operatorname{ran}\left(F_{\beta} \upharpoonright\left[B_{0}\left[E, e_{\beta}\right] \backslash \gamma\right]^{<\omega}\right)$
is not in $J_{\delta}$.
Now admittedly the previous claim is quite a lot to digest, so we will take a little time to illuminate the basic situation we have in mind.

Claim 2.2. The assumptions of Claim 2.1 are satisfied if
(1) $\lambda=\mu^{+}$where $\kappa=\operatorname{cf}(\mu)<\mu$
(2) $S \subseteq\{\delta<\lambda: \operatorname{cf}(\delta)=\kappa\}$
(3) $\delta \in S \rightarrow|\delta|=\mu$ (i.e., $S \subseteq \lambda \backslash \mu$ )
(4) $\bar{C}$ is an $S$-club system
(5) $\bar{J}=\left\langle J_{\delta}: \delta \in S\right\rangle$ where $J_{\delta}=J_{C_{\delta}}^{b[\mu]}$
(6) $\operatorname{id}_{p}(\bar{C}, \bar{J})$ is a proper ideal
(7) $\left\langle\kappa_{i}: i<\kappa\right\rangle$ is a non-decreasing sequence of cardinals with supremum $\kappa^{*} \leq \mu$
(8) $\gamma^{*}<\mu$, and for each $i<\kappa$, Player I wins the game $\operatorname{Gm}^{\omega}\left[\theta, \kappa_{i}, \gamma^{*}\right]$ for all large enough regular $\theta<\mu$
(9) $\bar{e}$ is a $\lambda$-club system such that $\left|e_{\beta}\right|<\mu$
(10) for $\alpha<\lambda, I_{\alpha}=J_{e_{\alpha}}^{\mathrm{bd}}$

Proof of Claim 2.2. We need only check items (2) and (3) in the statement of Claim 2.1 - everything else is trivially satisfied. Concerning (2), given $\delta \in S$ and $i<\kappa$, we need to show

$$
\left\{\alpha \in \operatorname{nacc}\left(C_{\delta}\right): \text { Player I wins } \operatorname{Gm}^{\omega}\left[e_{\alpha}, \kappa_{i}, \gamma^{*}\right]\right\}=\operatorname{nacc}\left(C_{\delta}\right) \quad \bmod J_{\delta} .
$$

Let $A$ consist of those $\alpha \in \operatorname{nacc}\left(C_{\delta}\right)$ for which Player I does not win the game $\mathrm{Gm}^{\omega}\left[e_{\alpha}, \kappa_{i}, \gamma^{*}\right]$. By our assumptions, there is a $\theta<\mu$ such that $\left|e_{\alpha}\right|<\theta$ for all $\alpha \in A$, and therefore $A$ is in the ideal $J_{C_{\delta}}^{b[\mu]}=J_{\delta}$ and we have what we need.

Concerning (3), given $E \subseteq \lambda$ club, we must find stationarily many $\delta \in S$ such that

$$
\left\{\alpha \in \operatorname{nacc}\left(C_{\delta}\right): B_{0}\left[E, e_{\alpha}\right] \notin I_{\alpha}\right\} \notin J_{\delta} .
$$

Let $E^{\prime}=\{\xi \in E: \operatorname{otp}(E \cap \xi)=\xi$ and $\mu$ divides $\xi\}$. Clearly $E^{\prime}$ is a closed unbounded subset of $E$, and since $\operatorname{id}_{p}(\bar{C}, \bar{J})$ is a proper ideal, the set

$$
S^{*}:=\left\{\delta \in S \cap E^{\prime}: E^{\prime} \cap \operatorname{nacc}\left(C_{\delta}\right) \notin J_{\delta}\right\}
$$

is stationary.
Fix $\delta \in S^{*}$, and suppose we are given $\theta<\mu$ and $\xi<\delta$. Since $E^{\prime} \cap \operatorname{nacc}\left(C_{\delta}\right) \notin$ $J_{\delta}$, we can find $\alpha \in E^{\prime} \cap \operatorname{nacc}\left(C_{\delta}\right)$ such that $\alpha>\max \{\xi, \mu\}$ and $\operatorname{cf}(\alpha)>\theta$. Since the order-type of $E \cap \alpha$ is $\alpha \geq \mu>\left|e_{\alpha}\right|$, we know that $B_{0}\left[E, e_{\alpha}\right]$ is unbounded in $e_{\alpha}$ hence a member of $I_{\alpha}$. This shows that the set of such $\alpha$ is in $J_{\delta}^{+}$, as required.

Now we return to the proof of Claim 2.1.
Proof of Claim 2.1. Let $\sigma=\operatorname{cf}(\sigma)$ be a regular cardinal $<\mu$ that is greater than $\mu^{*}$ and $\gamma^{*}$. For each limit $\beta<\lambda$, if there is an $i \leq \kappa$ such that Player I wins the version of $\mathrm{Gm}_{I_{\beta}}^{\omega}\left[e_{\beta}, \kappa_{i}, \sigma^{+}\right]$where we allow Player II to pass, then we let $h(\beta)$ be the maximal such $i$ - note that $i$ exists by (5) of Claim 1.3 - and let $\operatorname{Str}_{\beta}$ be a strategy that witnesses this.

Note that since $\gamma^{*}<\sigma^{+}$and $J_{\delta}=J_{\delta}^{b[\mu]}$ for $\delta \in S$, we have that for $\delta \in S$ and $i<\kappa$ that

$$
\left\{\beta \in \operatorname{nacc}\left(C_{\delta}\right): \operatorname{Str}_{\beta} \text { is defined and } i \leq h(\beta)\right\}=\operatorname{nacc}\left(C_{\delta}\right) \bmod J_{\delta}
$$

We will make $\sigma^{+}$attempts to build $\bar{F}$ witnessing the conclusion. In stage $\zeta<$ $\sigma^{+}$, we assume that our prior work has furnished us with a decreasing sequence $\left\langle E_{\xi}: \xi<\zeta\right\rangle$ of clubs in $\lambda$, and, for each $\beta<\lambda$ where $\operatorname{Str}_{\beta}$ is defined, an initial segment $\left\langle F_{\beta}^{\xi}, A_{\beta}^{\xi}: \xi<\zeta\right\rangle$ of a play of $\operatorname{Gm}_{I_{\beta}}^{\omega}\left[e_{\beta}, \kappa_{h(\beta)}^{*}, \sigma^{+}\right]$in which Player I uses $\operatorname{Str}_{\beta}$. (Note that our convention is that if Player II chooses to pass at a stage, we let $A_{\beta}^{\xi}$ be undefined.)

For each such $\beta$, let $F_{\beta}^{\zeta}:\left[e_{\beta}\right]^{<\omega} \rightarrow \kappa_{h(\beta)}$ be given by $\operatorname{Str}_{\beta}$, and for those $\beta$ for which $\operatorname{Str}_{\beta}$ is undefined, we let $F_{\zeta}^{\beta}$ be any such function. Now if $\left\langle F_{\beta}^{\zeta}: \beta<\lambda\right\rangle:=$
$\bar{F}^{\zeta}$ is as required then we are done. Otherwise, there is a club $E^{\prime} \subseteq \lambda$ and $i_{\zeta}<\kappa$ exemplifying the failure of $\bar{F}^{\zeta}$, and without loss of generality,

$$
\begin{equation*}
(\forall \delta \in S)\left[B_{i_{\zeta}}\left[E_{\zeta}^{\prime}, C_{\delta}, \bar{I}, \bar{e}, \bar{F}^{\zeta}\right]\right] \in J_{\delta} . \tag{2.2}
\end{equation*}
$$

Now let $E_{\zeta}=\operatorname{acc}\left(E_{\zeta}^{\prime} \cap \bigcap_{\xi<\zeta} E_{\xi}\right)$. For each $\beta$ where $\operatorname{Str}_{\beta}$ is defined, we let Player II respond to $F_{\beta}^{\zeta}$ by playing the set $B_{0}\left[E_{\zeta}, e_{\beta}\right]$ if it is a legal move, otherwise we let him pass. We then proceed to stage $\zeta+1$.

Assuming that this construction continues for all $\sigma^{+}$stages, we will arrive at a contradiction. Let $E=\bigcap_{\zeta<\sigma^{+}} E_{\zeta}$. By assumption (3) there is a $\delta(*) \in S$ for which

$$
A_{1}:=\left\{\beta \in \operatorname{nacc}\left(C_{\delta(*)}\right): B_{0}\left[E, e_{\beta}\right] \notin I_{\beta}\right\} \notin J_{\delta(*)} .
$$

By assumption (2), we have

$$
A_{2}:=\left\{\beta \in A_{1}: \operatorname{Str}_{\beta} \text { is defined }\right\} \notin J_{\delta(*)} .
$$

For $\beta \in A_{2}$, look at the play $\left\langle F_{\beta}^{\zeta}, A_{\beta}^{\zeta}: \zeta<\sigma^{+}\right\rangle$. Since Player I wins, there is a $\zeta_{\beta}<\sigma^{+}$such that Player II passed at stage $\zeta$ for all $\zeta \geq \zeta_{\beta}$. Since $\sigma>\mu^{*}$ and $J_{\delta(*)}$ is $\mu^{*}$-based, for some $\zeta^{*}<\sigma^{+}$,

$$
A_{3}=\left\{\beta \in A_{1}: \operatorname{Str}_{\beta} \text { is defined and } \zeta_{\beta} \leq \zeta^{*}\right\} \notin J_{\delta(*)} .
$$

Now $E_{\zeta^{*}}$ was defined so that for some $i_{\zeta^{*}}$, for all $\delta \in S$,

$$
\begin{equation*}
B_{i_{\zeta^{*}}}\left[E_{\zeta^{*}}, C_{\delta}, \bar{I}, \bar{e}, \bar{F}^{\zeta^{*}}\right] \in J_{\delta}, \tag{2.3}
\end{equation*}
$$

but (again by assumption (2))

$$
A_{4}=\left\{\beta \in A_{1}: \operatorname{Str}_{\beta} \text { is defined, } \zeta_{\beta} \leq \zeta^{*}, \text { and } i_{\zeta^{*}} \leq h(\beta)\right\} \notin J_{\delta(*)}
$$

For $\beta \in A_{4}$, we know that at stage $\zeta^{*}$ of our play of $\mathrm{Gm}_{I_{\beta}}^{\omega}\left[e_{\beta}, \kappa_{h(\beta)}, \sigma^{+}\right]$the set $B_{0}\left[E_{\zeta^{*}}, e_{\beta}\right]$ was not a legal move. Since our sequence of clubs is decreasing, we know that $B_{0}\left[E_{\zeta^{*}}, e_{\beta}\right]$ is a subset of $B_{0}\left[E_{\xi}, e_{\beta}\right]$ for all $\left.\xi<\zeta^{*}\right]$, so we have

$$
B_{0}\left[E_{\zeta^{*}}, e_{\beta}\right] \subseteq \bigcap_{\xi<\zeta^{*}} A_{\beta}^{\xi}
$$

Since $\beta \in A_{1}$, we know that $B_{0}\left[E_{\zeta^{*}}, e_{\beta}\right] \notin I_{\beta}$. Thus the reason for $B_{0}\left[E_{\zeta^{*}}, e_{\beta}\right]$ being an illegal move must be that for all $\gamma<\beta$,

$$
\kappa_{h(\beta)}^{*} \subseteq \operatorname{ran}\left(F_{\beta}^{\zeta^{*}} \upharpoonright\left[B_{0}\left[E_{\zeta^{*}}, e_{\beta}\right] \backslash \gamma\right]^{<\omega}\right)
$$

All of these facts combine to tells us that $\beta \in B_{i_{\zeta^{*}}}\left[E_{\zeta^{*}}, C_{\delta}, \bar{I}, \bar{e}, \bar{F}^{\zeta^{*}}\right]$, and thus

$$
A_{4} \subseteq B_{i_{\zeta^{*}}}\left[E_{\zeta^{*}}, C_{\delta}, \bar{I}, \bar{e}^{*}, \bar{F}^{\zeta^{*}}\right] \notin J_{\delta(*)}
$$

contradicting (2.3).
The proofs in this section (and the next) can be considerably simplified if we are willing to restrict ourselves to the case $\kappa^{*}<\mu$, as we can dispense with the sequence $\left\langle\kappa_{i}: i<\kappa\right\rangle$.

## 3. Building the Coloring

We now come to the main point of this paper; we dedicate this section and the next to proving the following theorem.

Theorem 1. Assume $\lambda=\mu^{+}$, where $\mu$ is a singular cardinal of uncountable cofinality, say $\aleph_{0}<\kappa=\operatorname{cf}(\mu)<\mu$. Assume $\left\langle\kappa_{i}: i<\kappa\right\rangle$ is non-decreasing with supremum $\kappa^{*} \leq \mu$, and there is a $\gamma^{*}<\mu$ such that for each $i$, for every large enough regular $\theta<\mu$, Player I has a winning strategy in the game $\operatorname{Gm}^{\omega}\left[\theta, \kappa_{i}, \gamma^{*}\right]$. Then $\operatorname{Pr}_{1}\left(\lambda, \lambda, \kappa^{*}, \kappa\right)$ holds.

Let $\left\langle S_{i}: i<\kappa\right\rangle$ be a sequence of pairwise disjoint stationary subsets of $\{\delta<\lambda: \operatorname{cf}(\delta)=\kappa\}$. For $i<\kappa$, let $\bar{C}^{i}$ be an $S_{i}$-club system such that

- $\lambda \notin \operatorname{id}_{p}\left(\bar{C}^{i}, \bar{J}^{i}\right)$, where $\bar{J}^{i}=\left\langle J_{C_{\delta}^{i}}^{b[\mu]}: \delta \in S_{i}\right\rangle$
- for $\delta \in S_{i}, \operatorname{otp}\left(C_{\delta}^{i}\right)=\operatorname{cf}(\delta)=\kappa=\operatorname{cf}(\mu)$

Such ladder systems can be found by Claim 2.6 (and Remark 2.6A (6)) of [2] — for the second statement to hold, we need that $\mu$ has uncountable cofinality.

Claim 3.1. There is a $\lambda$-club system $\bar{e}$ such that $\left|e_{\beta}\right| \leq \operatorname{cf}(\beta)+\operatorname{cf}(\mu)$, and $\bar{e}$ "swallows" each $\bar{C}^{i}$, i.e., if $\delta \in S_{i} \cap\left(e_{\beta} \cup\{\beta\}\right)$, then $C_{\delta}^{i} \subseteq e_{\beta}$.

Proof. Let $S=\cup_{i<\kappa} S_{i}$, and let $\beta<\lambda$ be a limit ordinal. Let $e_{\beta}^{0}$ be a closed cofinal subset of $\beta$ of order-type $\operatorname{cf}(\beta)$. We will construct the required ladder $e_{\beta}$ in $\omega$-stages, with $e_{\beta}^{n}$ denoting the result of the first $n$ stages of our procedure. The construction is straightforward, but it is worthwhile to note that we need to use the fact that each member of $S$ has uncountable cofinality.

Given $e_{\beta}^{n}$, let us define

$$
\begin{equation*}
B_{n}=S \cap\left(e_{\beta}^{n} \cup\{\beta\}\right) . \tag{3.1}
\end{equation*}
$$

Now we let $e_{\beta}^{n+1}$ be the closure in $\beta$ of

$$
\begin{equation*}
e_{\beta}^{n} \cup \bigcup\left\{C_{\delta}: \delta \in B_{n}\right\} \tag{3.2}
\end{equation*}
$$

Note that $\left|e^{n+1}\right| \leq \operatorname{cf}(\mu)+\operatorname{cf}(\beta)$ as $\left|C_{\delta}\right|=\operatorname{cf}(\mu)=\kappa$ for each $\delta \in S$. Finally, we let $e_{\beta}$ be the closure of $\cup_{n<\omega} e_{\beta}^{n}$ in $\beta$.

Clearly $\left|e_{\beta}\right| \leq \operatorname{cf}(\mu)+\operatorname{cf}(\beta)$. Also, since each element of $S$ has uncountable cofinality, if $\delta \in S \cap e_{\beta}$, then there is an $n$ such that $\delta \in e_{\beta}^{n}$, and therefore

$$
\begin{equation*}
C_{\delta} \subseteq e_{\beta}^{n+1} \subseteq e_{\beta} \tag{3.3}
\end{equation*}
$$

as required.
For each $i<\kappa$, there are $h_{i}$ and $\bar{F}^{i}=\left\langle F_{\delta}^{i}: \delta<\lambda, \delta\right.$ limit $\rangle$ as in the conclusion of Claim 2.1 applied to $\bar{C}^{i}$ and $\bar{e}$; note that we satisfy the assumptions of Claim 2.1 by way of Claim 2.2.

Let $\left\langle\lambda_{i}: i<\kappa\right\rangle$ be a strictly increasing sequence of regular cardinals $>\kappa$ and cofinal in $\mu$ such that

$$
\begin{equation*}
\lambda=\operatorname{tcf}\left(\prod_{i<\kappa} \lambda_{i} / J_{\kappa}^{\mathrm{bd}}\right), \tag{3.4}
\end{equation*}
$$

and let $\left\langle f_{\alpha}: \alpha<\lambda\right\rangle$ exemplify this. Finally, let $h_{0}^{*}: \kappa \rightarrow \omega$ and $h_{1}^{*}: \kappa \rightarrow \kappa$ be such that

$$
\begin{equation*}
(\forall n)(\forall i<\kappa)\left(\exists^{\kappa} j<\kappa\right)\left[h_{0}^{*}(j)=n \text { and } h_{1}^{*}(j)=i\right] . \tag{3.5}
\end{equation*}
$$

Before we can define our coloring, we must recall some of the terminology of [2].

Definition 3.2. Let $0<\alpha<\beta<\lambda$, and define

$$
\gamma(\alpha, \beta)=\min \left\{\gamma \in e_{\beta}: \gamma \geq \alpha\right\} .
$$

We also define (by induction on $\ell$ )

$$
\begin{gathered}
\gamma_{0}(\alpha, \beta)=\beta \\
\gamma_{\ell+1}(\alpha, \beta)=\gamma\left(\alpha, \gamma_{\ell}(\alpha, \beta)\right)(\text { if defined }) .
\end{gathered}
$$

We let $k(\alpha, \beta)$ be the first $\ell$ for which $\gamma_{\ell}(\alpha, \beta)=\alpha$. The sequence $\left\langle\gamma_{i}(\alpha, \beta): i \leq\right.$ $k(\alpha, \beta)\rangle$ will be referred to as the walk from $\beta$ to $\alpha$ along the ladder system $\bar{e}$.

We now define the coloring $c$ that will witness $\operatorname{Pr}_{1}\left(\lambda, \lambda, \kappa^{*}, \kappa\right)$. Recall that $c$ must be a symmetric two-place function from $\lambda$ to $\kappa^{*}$.

Given $\alpha<\beta$, we let $i=i(\alpha, \beta)$ be the maximal $j<\kappa$ such that $f_{\beta}(j)<f_{\alpha}(j)$ (if such an $j$ exists). Next, we walk from $\beta$ down to $\alpha$ along $\bar{e}$ until we reach an ordinal $\nu(\alpha, \beta)$ such that

$$
f_{\alpha}(i)<f_{\nu(\alpha, \beta)}(i),
$$

(again, if such an ordinal exists.) After this, we walk along $\bar{e}$ from $\alpha$ toward the ordinal $\max \left(\alpha \cap e_{\nu(\alpha, \beta)}\right)$ until we reach an ordinal $\eta(\alpha, \beta)$ for which

$$
f_{\nu(\alpha, \beta)}(i)<f_{\eta(\alpha, \beta)}(i)
$$

The idea now is to look at how the ladders $e_{\nu(\alpha, \beta)}$ and $e_{\eta(\alpha, \beta)}$ intertwine. Let us make a temporary definition by calling an ordinal $\xi \in e_{\nu(\alpha, \beta)}$ relevant if $e_{\eta(\alpha, \beta)}$ meets the interval $\left(\sup \left(\xi \cap e_{\nu(\alpha, \beta)}\right), \xi\right)$.

If it makes sense, we let $w(\alpha, \beta) \subseteq e_{\nu(\alpha, \beta)}$ be the last $h_{0}^{*}(i(\alpha, \beta))$ relevant ordinals in $e_{\nu(\alpha, \beta)}$ (so we need that the relevant ordinals have order-type $\gamma+h_{0}^{*}(i(\alpha, \beta))$ for some $\gamma$ ).

Finally, we define our coloring by

$$
\begin{equation*}
c(\alpha, \beta)=F_{\nu(\alpha, \beta)}^{h_{1}^{*}(i(\alpha, \beta))}(w(\alpha, \beta)) . \tag{3.6}
\end{equation*}
$$

If the attempt to define $c(\alpha, \beta)$ breaks down at some point for some specific $\alpha<\beta$, then we set $c(\alpha, \beta)=0$.

We now prove that this coloring works, so suppose $\left\langle t_{\alpha}: \alpha<\lambda\right\rangle$ are pairwise disjoint subsets of $\lambda$ such that $\left|t_{\alpha}\right|=\theta_{1}<\kappa$ and $j^{*}<\kappa^{*}$, and without loss of generality $\alpha<\min t_{\alpha}$ and $\theta_{1} \geq \omega$. We need to find $\delta_{0}$ and $\delta_{1}$ such that

$$
\begin{equation*}
\alpha \in t_{\delta_{0}} \text { and } \beta \in t_{\delta_{1}} \Rightarrow \alpha<\beta \text { and } c(\alpha, \beta)=j^{*} \tag{3.7}
\end{equation*}
$$

Let $j_{1}$ be the least $j$ such that $j^{*}<\kappa_{j}$, and let $S, \bar{C}$, and $\bar{F}$ denote $S_{j_{1}}, \bar{C}^{j_{1}}$, and $\bar{F}^{j_{1}}$ respectively.

Given $\delta<\lambda$, we define the envelope of $t_{\delta}\left(\right.$ denoted env $\left.\left(t_{\delta}\right)\right)$ by the formula

$$
\begin{equation*}
\operatorname{env}\left(t_{\delta}\right)=\bigcup_{\zeta \in t_{\delta}}\left\{\gamma_{\ell}(\delta, \zeta): \ell \leq k(\delta, \zeta)\right\} \tag{3.8}
\end{equation*}
$$

The envelope of $t_{\delta}$ is the set of all ordinals obtained by walking down to $\delta$ from some $\zeta \in t_{\delta}$ using the ladder system $\bar{e}$. This makes sense as we have arranged that $\delta<\min t_{\delta}$. Note also that $\left|\operatorname{env}\left(t_{\delta}\right)\right| \leq\left|t_{\delta}\right|=\theta_{1}$.

Next we define functions $g_{\delta}^{\min }$ and $g_{\delta}^{\max }$ in $\prod_{i<\kappa} \lambda_{i}$ by

$$
\begin{equation*}
g_{\delta}^{\min }(i)=\min \left\{f_{\gamma}(i): \gamma \in \operatorname{env}\left(t_{\delta}\right)\right\}, \tag{3.9}
\end{equation*}
$$

and

$$
\begin{equation*}
g_{\delta}^{\max }(i)=\sup \left\{f_{\gamma}(i)+1: \gamma \in \operatorname{env}\left(t_{\delta}\right)\right\} \tag{3.10}
\end{equation*}
$$

Note that $g_{\delta}^{\max }$ is well-defined as we assume that $\kappa<\min \left\{\lambda_{i}: i<\kappa\right\}$.
The following claim is quite easy, and the proof is left to the reader.
Claim 3.3.
(1) $f_{\delta}={ }_{J_{k}^{\text {bd }}} g_{\delta}^{\text {min }}$
(2) $g_{\delta}^{\min }(i) \leq g_{\delta}^{\max }(i)$ for all $i<\kappa$
(3) There is a $\delta^{\prime}>\delta$ such that $g_{\delta}^{\max } \leq_{J_{\kappa}^{\text {bd }}} g_{\delta^{\prime}}^{\min }$.

Now let $\chi^{*}=\left(2^{\lambda}\right)^{+}$, and let $\left\langle M_{\alpha}: \alpha<\lambda\right\rangle$ be a sequence of elementary submodels of $\left\langle H\left(\chi^{*}\right), \in,<_{\chi^{*}}^{*}\right\rangle$ that is increasing and continuous in $\alpha$ and such that each $M_{\alpha} \cap \lambda$ is an ordinal, $\left\langle M_{\beta}: \beta \leq \alpha\right\rangle \in M_{\alpha+1}$, and $\left\langle f_{\alpha}: \alpha<\lambda\right\rangle, g, c, \bar{e}, S, \bar{C}$, $\left\langle t_{\alpha}: \alpha<\lambda\right\rangle$ all belong to $M_{0}$. Note that $\mu+1 \subseteq M_{0}$.

The set $E=\left\{\alpha<\lambda: M_{\alpha} \cap \lambda=\alpha\right\}$ is closed unbounded in $\lambda$, and furthermore,

$$
\begin{equation*}
\alpha<\delta \in E \Rightarrow \sup t_{\alpha}<\delta \tag{3.11}
\end{equation*}
$$

By the choice of $\bar{C}$ and $\bar{F}$, for some $\delta \in S \cap E$ we have the set

$$
\begin{equation*}
A=\left\{\beta \in \operatorname{nacc}\left(C_{\delta}\right):(\forall \gamma<\beta) \operatorname{ran}\left(F_{\beta} \upharpoonright\left[B_{0}\left[E, e_{\beta}\right] \backslash \gamma\right]^{<\omega}\right) \supseteq \kappa_{j_{1}}\right\} \tag{3.12}
\end{equation*}
$$

is not in $J_{C_{\delta}}^{b[\mu]}$.
Note that $A \subseteq \operatorname{acc}(E)$, as $B_{0}\left[E, e_{\beta}\right]$ is unbounded in $\beta$ for $\beta \in A$. For $\beta \in t_{\delta}$, if $\ell<k(\delta, \beta)$ then $e_{\gamma_{\ell}(\delta, \beta)} \cap \delta$ is bounded in $\delta$, and since it is closed it has a well-defined maximum. Since $\left|t_{\delta}\right|<\kappa=\operatorname{cf}(\delta)$, this means the ordinal

$$
\gamma^{\otimes}:=\sup \left\{\max \left[e_{\gamma \ell}(\delta, \beta) \cap \delta\right]: \beta \in t_{\delta} \text { and } \ell<k(\delta, \beta)\right\}
$$

is strictly less than $\delta$.

For $\beta \in t_{\delta}$, let us define

$$
\begin{equation*}
A_{\beta}:=\left\{\beta^{\prime} \in A:(\exists \ell \leq k(\beta, \delta))\left[\operatorname{cf}\left(\beta^{\prime}\right) \leq\left|e_{\gamma \ell}(\delta, \beta)\right|\right]\right\} . \tag{3.13}
\end{equation*}
$$

Since the cardinality of each ladder in $\bar{e}$ is less than $\mu$, each set $A_{\beta}$ is an element of $J_{C_{\delta}}^{b[\mu]}$. The ideal $J_{C_{\delta}}^{b[\mu]}$ is $\kappa$-complete, so the fact that $\left|t_{\delta}\right|<\kappa$ and $k(\beta, \delta)$ is finite for each $\beta \in t_{\delta}$ together imply that

$$
\begin{equation*}
\bigcup_{\beta \in t_{\delta}} A_{\beta} \in J_{C_{\delta}}^{b[\mu]} \tag{3.14}
\end{equation*}
$$

By the definition of $A$ and our choice of $\delta$, this means it is possible to choose $\beta^{*} \in A \backslash\left(\gamma^{\otimes}+1\right)$ that is not in any $A_{\beta}$, i.e.,

$$
\begin{equation*}
\beta \in t_{\delta} \text { and } \ell<k(\delta, \beta) \Longrightarrow \operatorname{cf}\left(\beta^{*}\right)>\left|e_{\gamma_{\ell}(\delta, \beta)}\right| . \tag{3.15}
\end{equation*}
$$

Claim 3.4.
(1) If $\epsilon \in t_{\delta}$, and $\ell=k(\delta, \epsilon)-1$, then $\beta^{*} \in \operatorname{nacc}\left(e_{\gamma_{\ell}(\delta, \epsilon)}\right)$.
(2) If $\epsilon \in t_{\delta}$ and $\gamma^{\otimes}<\gamma^{\prime} \leq \beta^{*}$, then

- $\gamma_{\ell}(\delta, \epsilon)=\gamma_{\ell}\left(\gamma^{\prime}, \epsilon\right)$ for $\ell<k(\delta, \epsilon)$, and
- $\gamma_{k(\delta, \epsilon)}\left(\gamma^{\prime}, \epsilon\right)=\beta^{*}$

Proof. For the first clause, note that $\delta$ is an element of $e_{\gamma_{\ell}(\delta, \epsilon)}$ and hence by our choice of $\bar{e}, C_{\delta} \subseteq e_{\gamma_{\ell}(\delta, \epsilon)}$. Thus $\beta^{*} \in e_{\gamma_{\ell}(\delta, \epsilon)}$, and since $\operatorname{cf}\left(\beta^{*}\right)>\left|e_{\gamma_{\ell}(\delta, \epsilon)}\right|$, we know that $\beta^{*}$ cannot be an accumulation point of $e_{\ell \ell}(\delta, \epsilon)$.

The first part of the second statement follows because of the definition of $\gamma^{\otimes}$. As far as the second part of the second statement goes, it is best visualized as follows:

We walk down the ladder system $\bar{e}$ from $\epsilon$ to $\gamma^{\prime}$, we eventually hit a ladder that contains $\delta$ - this happens at stage $k(\delta, \epsilon)-1$. Since $C_{\delta}$ is a subset of this ladder, the next step in our walk from $\epsilon$ to $\gamma^{\prime}$ must be down to $\beta^{*}$ because $\gamma^{\otimes}<$ $\gamma^{\prime}<\beta^{*}$.

We can visualize the preceding claim in the following manner: $\beta^{*}$ is chosen so that for all sufficiently large $\gamma^{\prime}<\beta^{*}$, all the walks from some element of $t_{\delta}$ to $\gamma^{\prime}$ are funnelled through $\beta^{*}-\beta^{*}$ acts as a bottleneck. This will be key when want to prove that our coloring works.

Since $\beta^{*} \in A$, we can choose a finite increasing sequence $\xi_{0}<\xi_{1}<\cdots<\xi_{n}$ of ordinals in $\operatorname{acc}(E) \cap \operatorname{nacc}\left(e_{\beta^{*}}\right) \backslash\left(\gamma^{\otimes}+1\right)$ such that $F_{\beta^{*}}^{j_{1}}\left(\left\{\xi_{0}, \ldots, \xi_{n}\right\}\right)=j^{*}$, the color we are aiming for.

For each $\ell \leq n$, we can find $\zeta_{\ell} \in E \backslash\left(\gamma^{\otimes}+1\right)$ such that

$$
\sup \left(e_{\beta^{*}} \cap \xi_{\ell}\right)<\zeta_{\ell}<\xi_{\ell}
$$

Now we let $\phi\left(x_{0}, y_{0}, x_{1}, y_{1}, \ldots, x_{n}, y_{n}, z_{0}, z_{1}\right)$ be the formula (with parameters $\left.\gamma^{\otimes}, \bar{f},\left\langle\lambda_{i}: i<\kappa\right\rangle, \bar{C}, \bar{e},\left\langle t_{\alpha}: \alpha<\lambda\right\rangle, h, h_{0}, j^{*}\right)$ that describes our current situation with $x_{\ell}, y_{\ell}$ standing for $\zeta_{\ell}, \xi_{\ell}$, and $z_{0}, z_{1}$ standing for $\beta^{*}, \delta$, i.e., $\phi$ states

- $\gamma^{\otimes}<x_{0}<y_{0}<\cdots<x_{n}<y_{n}<z_{0}<z_{1}$ are ordinals $<\lambda$
- $z_{1} \in S$ and $z_{0} \in \operatorname{nacc}\left(C_{z_{1}}\right)$
- $\gamma^{\otimes}=\sup \left\{\max \left[e_{\gamma \ell\left(z_{1}, \zeta\right)} \cap z_{1}\right]: \ell<k\left(z_{1}, \zeta\right)\right.$ and $\left.\zeta \in t_{z_{1}}\right\}$
- $z_{0} \in \operatorname{nacc}\left(e_{\gamma_{k\left(z_{1}, \epsilon\right)}\left(z_{1}, \epsilon\right)}\right)$ for all $\epsilon \in t_{z_{1}}$
- $F_{z_{0}}^{j_{1}}\left(\left\{y_{0}, \ldots, y_{n}\right\}\right)=j^{*}$

Now clearly we have

$$
\begin{equation*}
H(\chi) \vDash \phi\left[\zeta_{0}, \xi_{0}, \ldots, \zeta_{n}, \xi_{n}, \beta^{*}, \delta\right] . \tag{3.16}
\end{equation*}
$$

Recall that all the parameters needed in $\phi$ are in $M_{0}$, except possibly for $\gamma^{\otimes}$, so the model $M_{\gamma^{\otimes+1}}$ contains all the parameters we need. Also, $\left\{\zeta_{0}, \xi_{0}, \ldots, \zeta_{n}, \xi_{n}\right\} \in$ $M_{\beta^{*}}, \beta^{*} \in M_{\delta} \backslash M_{\beta^{*}}$, and since $\delta \in \lambda \backslash M_{\delta}$, we have (recalling that $\exists^{*} z<\lambda$ means "for unboundedly many $z<\lambda$ )

$$
\begin{equation*}
M_{\delta} \models\left(\exists^{*} z_{1}<\lambda\right) \phi\left(\zeta_{0}, \xi_{0}, \ldots, \zeta_{n}, \xi_{n}, \beta^{*}, z_{1}\right) . \tag{3.17}
\end{equation*}
$$

Therefore, this formula is true in $H(\chi)$ because of elementarity. Similarly, we have

$$
H(\chi) \models\left(\exists^{*} z_{0}<\lambda\right)\left(\exists^{*} z_{1}<\lambda\right) \phi\left(\zeta_{0}, \xi_{0}, \ldots, \zeta_{n}, \xi_{n}, z_{0}, z_{1}\right) .
$$

Now each of the intervals $\left[\gamma^{\otimes}+1, \zeta_{0}\right),\left[\zeta_{0}, \xi_{0}\right), \ldots$, contains a member of $E$, so (by the definition of $E$ ) similar considerations give us
$H(\chi) \models\left(\exists^{*} x_{0}<\lambda\right) \ldots\left(\exists^{*} y_{n}<\lambda\right)\left(\exists^{*} z_{0}<\lambda\right)\left(\exists^{*} z_{1}<\lambda\right) \phi\left(x_{0}, y_{0}, \ldots, z_{0}, z_{1}\right)$.
Now we can choose (in order)

$$
\begin{equation*}
\zeta_{0}^{a}<\zeta_{0}^{b}<\xi_{0}^{a}<\zeta_{1}^{a}<\xi_{0}^{b}<\zeta_{1}^{b}<\cdots<\zeta_{n}^{a}<\xi_{n-1}^{b}<\zeta_{n}^{b}<\xi_{n}^{a} \tag{3.18}
\end{equation*}
$$

such that

$$
\begin{equation*}
\left(\exists^{*} z_{0}<\lambda\right)\left(\exists^{*} z_{1}<\lambda\right)\left[\phi\left(\zeta_{0}^{a}, \ldots, \xi_{n-1}^{a}, \zeta_{n}^{a}, \xi_{n}^{a}, z_{0}, z_{1}\right)\right], \tag{3.19}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(\exists^{*} y_{n}<\lambda\right)\left(\exists^{*} z_{0}<\lambda\right)\left(\exists^{*} z_{1}<\lambda\right)\left[\phi\left(\zeta_{0}^{b}, \ldots, \xi_{n-1}^{b}, \zeta_{n}^{b}, y_{n}, z_{0}, z_{1}\right)\right] \tag{3.20}
\end{equation*}
$$

Our goal is to show that for all sufficiently large $i<\kappa$, it is possible to choose objects $\beta^{a}, \delta^{a}, \xi_{n}^{b}, \beta^{b}$, and $\delta^{b}$ such that

## Table 1

(1) $\zeta_{n}^{b}<\beta^{a}<\delta^{a}<\min \left(t_{\delta^{a}}\right) \leq \max \left(t_{\delta^{a}}\right)<\xi_{n}^{b}<\beta^{b}<\delta^{b}$
(2) $\phi\left(\zeta_{0}^{a}, \ldots, \xi_{n}^{a}, \beta^{a}, \delta^{a}\right)$
(3) $\phi\left(\zeta_{0}^{b}, \ldots, \xi_{n}^{b}, \beta^{b}, \delta^{b}\right)$
(4) for all $\epsilon \in \operatorname{env}\left(t_{\delta^{a}}\right), g_{\delta^{a}}^{\min } \upharpoonright[i, \kappa) \leq f_{\epsilon} \upharpoonright[i, \kappa) \leq g_{\delta^{a}}^{\max } \upharpoonright[i, \kappa)$
(5) for all $\epsilon \in \operatorname{env}\left(t_{\delta^{b}}\right), g_{\delta^{b}}^{\min } \upharpoonright[i, \kappa) \leq f_{\epsilon} \upharpoonright[i, \kappa) \leq g_{\delta^{b}}^{\max } \upharpoonright[i, \kappa)$
(6) $g_{\delta^{b}}^{\max }(i)<g_{\delta^{a}}^{\min }(i) \leq g_{\delta^{a}}^{\max }(i)<f_{\beta^{b}}(i)<f_{\beta^{a}}(i)$
(7) $g_{\delta^{a}}^{\max } \upharpoonright[i+1, \kappa)<g_{\delta^{b}}^{\min } \upharpoonright[i+1, \kappa)$

Claim 3.5. If for all sufficiently large $i<\kappa$ it is possible to find objects satisfying the requirements of Table 1 , then we can find $\delta^{a}<\delta^{b}$ such that $c\left(\epsilon^{a}, \epsilon^{b}\right)=j^{*}$ for all $\epsilon^{a} \in t_{\delta^{a}}$ and $\epsilon^{b} \in t_{\delta^{b}}$.

Proof. Let us choose $i^{*}<\kappa$ such that

- suitable objects (as above) can be found, and
- $h_{1}^{*}\left(i^{*}\right)=j_{1}$ and $h_{0}^{*}\left(i^{*}\right)=n$

Choose $\epsilon^{a} \in t_{\delta^{a}}$ and $\epsilon^{b} \in t_{\delta^{b}}$; we verify that $c\left(\epsilon^{a}, \epsilon^{b}\right)=j^{*}$.
Subclaim 1. $i\left(\epsilon^{a}, \epsilon^{b}\right)=i^{*}$.
Proof. Immediate by (4)-(7) in the table.
Subclaim 2. $\nu\left(\epsilon^{a}, \epsilon^{b}\right)=\beta^{b}$.
Proof. Note that $\gamma^{\otimes}<\epsilon^{a}<\beta^{b}$. Clause (3) of the table implies that the assumptions of Claim 3.4 hold. Thus by Claim 3.4, for $\ell<k\left(\delta^{b}, \epsilon^{b}\right)$ we have

$$
\gamma_{\ell}\left(\epsilon^{a}, \epsilon^{b}\right)=\gamma_{\ell}\left(\delta^{b}, \epsilon^{b}\right),
$$

hence $\gamma_{\ell}\left(\epsilon^{a}, \epsilon^{b}\right) \in \operatorname{env}\left(t_{\delta^{b}}\right)$ and (by (6) of the table and the definitions involved)

$$
\begin{equation*}
f_{\gamma_{\ell}\left(\epsilon^{a}, \epsilon^{b}\right)}\left(i^{*}\right) \leq g_{\delta^{b}}^{\max }\left(i^{*}\right)<g_{\delta^{a}}^{\min }\left(i^{*}\right) \leq f_{\epsilon^{a}}\left(i^{*}\right) . \tag{3.21}
\end{equation*}
$$

For $\ell=k\left(\delta^{b}, \epsilon^{b}\right)$, Claim 3.4 tells us

$$
\gamma_{\ell}\left(\epsilon^{a}, \epsilon^{b}\right)=\beta^{b},
$$

and we have arranged that

$$
\begin{equation*}
f_{\epsilon^{a}}\left(i^{*}\right) \leq g_{\delta^{a}}^{\max }\left(i^{*}\right)<f_{\beta^{b}}\left(i^{*}\right) . \tag{3.22}
\end{equation*}
$$

This establishes $\beta^{b}=\nu\left(\epsilon^{a}, \epsilon^{b}\right)$.
Subclaim 3. $\eta\left(\epsilon^{a}, \epsilon^{b}\right)=\beta^{a}$.
Proof. Let $\alpha=\max \left(e_{\beta^{b}} \cap \epsilon^{a}\right)$. We have arranged that

$$
\zeta_{n}^{b}<\beta^{a}<\delta^{a}<\epsilon^{a}<\xi_{n}^{b}
$$

and $\gamma^{\otimes}<\max \left(e_{\beta^{b}} \cap \delta^{a}\right)$, hence $\gamma^{\otimes}<\alpha<\beta^{a}$. For $\ell<k\left(\delta^{a}, \epsilon^{a}\right)$, Claim 3.4 implies

$$
\gamma_{\ell}\left(\alpha, \epsilon^{a}\right)=\gamma_{\ell}\left(\delta^{a}, \epsilon^{a}\right) \in \operatorname{env}\left(t_{\delta^{a}}\right) .
$$

By our choice of $i^{*}$, we have

$$
\begin{equation*}
f_{\gamma_{\ell}\left(\alpha, \epsilon^{a}\right)}\left(i^{*}\right) \leq g_{\delta^{a}}^{\max }\left(i^{*}\right)<f_{\beta^{b}}\left(i^{*}\right) . \tag{3.23}
\end{equation*}
$$

For $\ell=k\left(\delta^{a}, \epsilon^{a}\right)$, Claim 3.4 implies $\gamma_{\ell}\left(\alpha, \epsilon^{a}\right)=\beta^{a}$, and we have ensured

$$
\begin{equation*}
f_{\beta^{b}}\left(i^{*}\right)<f_{\beta^{a}}\left(i^{*}\right) \tag{3.24}
\end{equation*}
$$

Thus $\beta^{a}$ is the first ordinal $\eta$ in the walk from $\epsilon^{a}$ to $\max \left(e_{\beta^{b}} \cap \epsilon^{a}\right)$ for which $f_{\eta}\left(i^{*}\right)>f_{\beta^{b}}\left(i^{*}\right)$, and therefore $\eta\left(\epsilon^{a}, \epsilon^{b}\right)=\beta^{a}$.

Subclaim 4. $w\left(\epsilon^{a}, \epsilon^{b}\right)=\left\{\xi_{0}^{b}, \ldots \xi_{n}^{b}\right\}$.
Proof. Our previous subclaims imply that an ordinal $\xi \in e_{\beta^{b}}$ is relevant if and only if the ladder $e_{\beta^{a}}$ meets the interval ( $\left.\sup \left(e_{\beta^{b}} \cap \xi\right), \xi\right)$. Since $h_{0}^{*}\left(i^{*}\right)=n+1$, we know that $w\left(\epsilon^{a}, \epsilon^{b}\right)$ consists of the last $n+1$ relevant ordinals in $e_{\beta^{b}}$.

For $i \leq n$, clearly $\xi_{i}^{b} \in e_{\beta^{b}}$ and $\sup \left(\xi_{i}^{b} \cap e_{\beta^{b}}\right) \leq \zeta_{n}^{b}$. We have made sure that $e_{\beta^{a}} \cap\left(\zeta_{i}^{b}, \xi_{i}^{b}\right) \neq \emptyset$ (for example, $\xi_{i}^{a}$ is an element in this intersection) and so each $\xi_{i}^{b}$ is relevant.

Since $\beta^{a}<\xi_{n}^{b}$, it is clear that there are no relevant ordinals larger than $\xi_{n}^{b}$.
Given $i<n$, if $\xi \in e_{\beta^{b}} \cap\left(\xi_{i}^{b}, \xi_{i+1}^{b}\right)$, then

$$
\xi_{i}^{b} \leq \sup \left(\xi \cap e_{\beta^{b}}\right) \leq \xi \leq \zeta_{i+1}^{b}
$$

Since $\zeta_{i+1}^{a}<\xi_{i}^{b}<\zeta_{i+1}^{b}<\xi_{i+1}^{a}$, it follows that

$$
\left[\sup \left(\xi \cap e_{\beta^{b}}\right), \xi\right) \subseteq\left[\zeta_{i+1}^{a}, \xi_{i+1}^{a}\right)
$$

and so $\xi$ is not relevant. Thus $\left\{\xi_{0}^{b}, \ldots, \xi_{n}^{b}\right\}$ are the last $n+1$ relevant elements of $e_{\beta^{b}}$, as was required.

To finish the proof of Claim 3.5, we note that as $h_{1}^{*}\left(i^{*}\right)=j^{*}$, we have

$$
\begin{equation*}
c\left(\epsilon^{a}, \epsilon^{b}\right)=F_{\beta^{b}}^{j_{1}}\left(\left\{\xi_{0}^{b}, \ldots, \xi_{n}^{b}\right\}\right)=j^{*} . \tag{3.25}
\end{equation*}
$$

## 4. Finding the required ordinals

The whole of this section will be occupied with showing that for all sufficiently large $i<\kappa$, it is possible to find objects satisfying the requirements of Table 1.

We begin with some notation intended to simplify the presentation.

- $\phi^{a}\left(z_{0}, z_{1}\right)$ abbreviates the formula $\phi\left(\zeta_{0}^{a}, \ldots, \xi_{n}^{a}, z_{0}, z_{1}\right)$
- $\phi^{b}\left(y_{n}, z_{0}, z_{1}\right)$ abbreviates the formula $\phi\left(\zeta_{0}^{b}, \zeta_{b}^{n}, y_{n}, z_{0}, z_{1}\right)$
- For $i<\kappa, \psi\left(i, z_{1}\right)$ abbreviates the formula

$$
\begin{equation*}
\left(\forall \epsilon \in \operatorname{env}\left(t_{z_{1}}\right)\right)\left[g_{z_{1}}^{\min } \upharpoonright[i, \kappa) \leq f_{\epsilon} \upharpoonright[i, \kappa) \leq g_{z_{1}}^{\max } \upharpoonright[i, \kappa)\right] \tag{4.1}
\end{equation*}
$$

We have arranged things so that the sentence

$$
\begin{align*}
\left(\exists^{*} z_{0}^{a}<\lambda\right)\left(\exists^{*} z_{1}^{a}<\lambda\right) & \left(\exists^{*} y_{n}^{b}<\lambda\right) \\
& \left(\exists^{*} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\phi^{a}\left(z_{0}^{a}, z_{1}^{a}\right) \wedge \phi^{b}\left(y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right] \tag{4.2}
\end{align*}
$$

holds.
There are far too many alternations of quantifiers in the above formula for most people to deal with comfortably; the best way to view them is as a single quantifier that asserts the existence of a tree of 5-tuples with the property that every node of
the tree has $\lambda$ successors, and every branch through the tree gives us five objects satisfying $\phi^{a} \wedge \phi^{b}$.

Let $\Phi\left(i, z_{0}^{a}, \ldots, z_{1}^{b}\right)$ abbreviate the formula

$$
\begin{aligned}
\phi^{a}\left(z_{0}^{a}, z_{1}^{a}\right) & \wedge \phi^{b}\left(y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right) \wedge \psi\left(i, z_{1}^{a}\right) \wedge \psi\left(i, z_{1}^{b}\right) \\
& \wedge\left(g_{z_{1}^{a}}^{\max } \upharpoonright[i+1, \kappa)<g_{z_{1}^{b}}^{\min } \upharpoonright[i+1, \kappa)\right) .
\end{aligned}
$$

By pruning the tree so that every branch through it is a strictly increasing 5-tuple, we get

$$
\begin{align*}
& \left(\exists^{*} z_{0}^{a}<\lambda\right)\left(\exists^{*} z_{1}^{a}<\lambda\right)\left(\exists^{*} y_{n}^{b}<\lambda\right) \\
&  \tag{4.3}\\
& \quad\left(\exists^{*} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left(\forall^{*} i<\kappa\right)\left[\Phi\left(i, z_{0}^{a}, \ldots, z_{1}^{b}\right)\right] .
\end{align*}
$$

We now make a rather ad hoc definition of another quantifier in an attempt to make the arguments that follow a little bit clearer. Given $i<\kappa$, let the quantifier $\exists^{*, i} z_{0}^{b}<\lambda$ mean that not only are there unboundedly many $z_{0}^{b}$, s below $\lambda$ satisfying whatever property, but also that for each $\alpha<\lambda_{i}$, we can find unboundedly many suitable $z_{0}^{b}$ 's for which $f_{z_{0}^{b}}(i)$ is greater than $\alpha$.

Claim 4.1. If we choose $\beta^{a}<\delta^{a}<\xi_{n}^{b}$ such that

$$
\begin{equation*}
\left(\exists^{*} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left(\forall^{*} i<\kappa\right)\left[\Phi\left(i, \beta^{a}, \delta^{a}, \xi_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right], \tag{4.4}
\end{equation*}
$$

then

$$
\begin{equation*}
\left(\forall^{*} i<\kappa\right)\left(\exists^{*, i} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, \delta^{a}, \xi_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right] . \tag{4.5}
\end{equation*}
$$

Proof. Suppose that we have $\beta^{a}<\delta^{a}<\xi_{n}^{b}$ such that (4.4) holds but (4.5) fails. Then there is an unbounded $I \subseteq \kappa$ such that for each $i \in I$,

$$
\begin{equation*}
\neg\left(\exists^{*, i} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, \delta^{a}, \xi_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right] . \tag{4.6}
\end{equation*}
$$

In (4.4), we can move the quantifier " $\forall^{*} i<\kappa^{\prime \prime}$ past the quantifiers to its left, i.e.,

$$
\begin{equation*}
\left(\forall^{*} i<\kappa\right)\left(\exists^{*} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, \delta^{a}, \xi_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right], \tag{4.7}
\end{equation*}
$$

so without loss of generality, for all $i \in I$,

$$
\begin{equation*}
\left(\exists^{*} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, \delta^{a}, \xi_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right] \tag{4.8}
\end{equation*}
$$

Since (4.6) holds for all $i \in I$, it must be the case that for each $i \in I$, there is a value $g(i)<\lambda_{i}$ such that for all sufficiently large $\beta<\lambda$, if

$$
\begin{equation*}
\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, \delta^{a}, \xi_{n}^{b}, \beta, z_{1}^{b}\right)\right], \tag{4.9}
\end{equation*}
$$

then

$$
\begin{equation*}
f_{\beta}(i) \leq g(i) . \tag{4.10}
\end{equation*}
$$

Since $\left\{f_{\alpha}: \alpha<\lambda\right\}$ witnesses that the true cofinality of $\prod_{i<\kappa} \lambda_{i}$ is $\lambda$, we know

$$
\begin{equation*}
\left(\forall^{*} x<\lambda\right)\left(\forall^{*} i \in I\right)\left[g(i)<f_{x}(i)\right] . \tag{4.11}
\end{equation*}
$$

When we combine this with (4.4), we see that it is possible to choose $\beta^{b}<\lambda$ such that

$$
\begin{equation*}
\left(\forall^{*} i \in I\right)\left[g(i)<f_{\beta^{b}}(i)\right], \tag{4.12}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(\exists^{*} z_{1}^{b}<\lambda\right)\left(\forall^{*} j<\kappa\right)\left[\Phi\left(j, \beta^{a}, \delta^{a}, \xi_{n}^{b}, \beta^{b}, z_{1}^{b}\right)\right] . \tag{4.13}
\end{equation*}
$$

(Note that we have quietly used the fact that $|I|<\lambda=\operatorname{cf}(\lambda)$ to get a $\beta^{b}$ that is "large enough" so that (4.9) implies (4.10) for all $i \in I$ for this particular $\beta^{b}$.) This last equation implies

$$
\left(\forall^{*} j<\kappa\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(j, \beta^{a}, \delta^{a}, \xi_{n}^{b}, \beta^{b}, z_{1}^{b}\right)\right]
$$

so it is possible to choose $i \in I$ large enough so that

$$
g(i)<f_{\beta^{b}}(i)
$$

and

$$
\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, \delta^{a}, \xi_{n}^{b}, \beta^{b}, z_{1}^{b}\right)\right] .
$$

This is a contradiction, as (4.9) holds for our choice of $i$ and $\beta=\beta^{b}$, yet (4.10) fails.

Notice that an immediate corollary of the preceding claim is

$$
\begin{align*}
\left(\exists^{*} z_{0}^{a}<\lambda\right)\left(\exists^{*} z_{1}^{a}<\lambda\right) & \left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\forall^{*} i<\kappa\right) \\
& \left(\exists^{*, i} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, \delta^{a}, \xi_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right] . \tag{4.14}
\end{align*}
$$

Claim 4.2. If $\beta^{a}<\lambda$ is chosen so that

$$
\begin{align*}
& \left(\exists^{*} z_{1}^{a}<\lambda\right)\left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\forall^{*} i<\kappa\right) \\
& \quad\left(\exists^{*, i} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right] \tag{4.15}
\end{align*}
$$

then

$$
\left(\forall^{*} i<\kappa\right)\left(\exists v<\lambda_{i}\right)\left(\exists^{*} z_{1}^{a}<\lambda\right)\left[\psi^{\prime} \wedge \psi^{\prime \prime}\right]
$$

where

$$
\psi^{\prime}:=g_{z_{1}^{a}}^{\max }(i)<v
$$

and

$$
\begin{aligned}
\psi^{\prime \prime}:= & \left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\exists^{*} z_{0}^{b}<\lambda\right) \\
& {\left[v<f_{z_{0}^{b}}(i) \text { and }\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right] . }
\end{aligned}
$$

Proof. In (4.15), we can move the quantifier " $\left(\forall^{*} i<\kappa\right)$ " past the other quantifiers to its left, so

$$
\begin{align*}
& \left(\forall^{*} i<\kappa\right)\left(\exists^{*} z_{1}^{a}<\lambda\right)\left(\exists^{*} y_{n}^{b}<\lambda\right) \\
& \quad\left(\exists^{*, i} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right] \tag{4.16}
\end{align*}
$$

holds. The claim will be established if we show that for each $i<\kappa$ for which

$$
\begin{align*}
& \left(\exists^{*} z_{1}^{a}<\lambda\right)\left(\exists^{*} y_{n}^{b}<\lambda\right) \\
& \quad\left(\exists^{*, i} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right] \tag{4.17}
\end{align*}
$$

holds, it is possible to find $v<\lambda_{i}$ such that

$$
\begin{align*}
& \left(\exists^{*} z_{1}^{a}<\lambda\right)\left[g_{z_{1}^{a}}^{\max }(i)<v\right. \text { and } \\
& \left.\left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\exists^{*} z_{0}^{b}<\lambda\right)\left[v<f_{z_{0}^{b}}(i) \text { and }\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right]\right] \tag{4.18}
\end{align*}
$$

Despite the lengths of the formulas involved, this is not that hard to accomplish. Since $\lambda_{i}<\lambda=\operatorname{cf}(\lambda)$, we can find $v<\lambda_{i}$ such that

$$
\begin{aligned}
& \left(\exists^{*} z_{1}^{a}<\lambda\right)\left[g_{z_{1}^{a}}^{\max }(i)<v\right. \text { and } \\
& \left.\left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\exists^{*, i} z_{0}^{b}<\lambda\right)\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right],
\end{aligned}
$$

and now the result follows from of the definition of " $\exists^{*, i} z_{1}^{b}<\lambda$ ".
Thus there are unboundedly many $z_{0}^{a}<\lambda$ for which there is a function $g \in$ $\prod_{i<\kappa} \lambda_{i}$ such that for all sufficiently large $i<\kappa$,

$$
\begin{align*}
& \left(\exists^{*} z_{1}^{a}<\lambda\right)\left[g_{z_{1}^{a}}^{\max }(i) \leq g(i)\right. \text { and } \\
& \left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\exists^{*} z_{0}^{b}<\lambda\right)\left[g(i)<f_{z_{0}^{b}}(i)\right. \\
& \left.\left.\quad \quad \text { and }\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, z_{0}^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right]\right] . \tag{4.19}
\end{align*}
$$

Now this is logically equivalent to the statement

$$
\begin{align*}
& \quad\left(\exists^{*} z_{1}^{a}<\lambda\right)\left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\exists^{*} z_{0}^{b}<\lambda\right) \\
& {\left[g_{z_{1}^{a}}^{\max }(i)\right.}\left.\leq g(i)<f_{z_{0}^{b}}(i) \text { and }\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, z_{0}^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right] . \tag{4.20}
\end{align*}
$$

Suppose we are given a particular $z_{0}^{a}<\lambda$ for which a function $g$ as above can be found, and let us fix $i<\kappa$ "large enough" so that (4.19) holds. Also fix ordinals $\delta^{a}<\lambda$ and $\xi_{n}^{b}<\lambda$ that serve as suitable $z_{1}^{a}$ and $y_{n}^{b}$. Just to be clear, this means that for these choices we have

$$
\left(\exists^{*} z_{0}^{b}<\lambda\right)\left[g_{\delta^{a}}^{\max }(i) \leq g(i)<f_{z_{0}^{b}}(i) \text { and }\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, \delta^{a}, \xi_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right] .
$$

Since $\lambda_{i}<\lambda=\operatorname{cf}(\lambda)$, there must be some value $w$ satisfying

$$
\left(\exists^{*} z_{0}^{b}<\lambda\right)\left[g(i)<f_{z_{0}^{b}}(i)<w \text { and }\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, \delta^{a}, \xi_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right] .
$$

This implies for our particular $\beta^{a}, g, i, \delta^{a}$, and $\xi_{n}^{b}$ that

$$
\begin{align*}
& \left(\forall^{*} w<\lambda_{i}\right)\left(\exists^{*} z_{0}^{b}<\lambda\right)\left[g_{\delta^{a}}^{\max }(i) \leq g(i)<f_{z_{1}^{b}}(i)<w\right. \text { and } \\
& \left.\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, \delta^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right] . \tag{4.21}
\end{align*}
$$

Since $\lambda_{i}<\lambda=\operatorname{cf}(\lambda)$, the quantifier $\left(\forall^{*} w<\lambda_{i}\right)$ can move to the left past the quantifiers $\left(\exists^{*} z_{1}^{a}<\lambda\right)\left(\exists^{*} y_{n}^{b}<\lambda\right)$. This tells us that for our $\beta^{a}$ and $g$,

$$
\begin{align*}
\left(\forall^{*} i\right. & <\kappa)\left(\forall^{*} w<\lambda_{i}\right)\left(\exists^{*} z_{1}^{a}<\lambda\right)\left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\exists^{*} z_{0}^{b}<\lambda\right) \\
{\left[g_{z_{1}^{a}}^{\max }(i)\right.} & \leq g(i)<f_{z_{0}^{b}}(i)<w \text { and } \\
\left(\exists^{*} z_{1}^{b}\right. & \left.<\lambda)\left[\Phi\left(i, \beta^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right] \tag{4.22}
\end{align*}
$$

When we put all this together, we end up with the statement

$$
\begin{gather*}
\left(\exists^{*} z_{0}^{a}<\lambda\right)\left(\forall^{*} i<\kappa\right)\left(\exists v<\lambda_{i}\right)\left(\forall^{*} w<\lambda_{i}\right)\left(\exists^{*} z_{1}^{a}<\lambda\right) \\
\left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\exists^{*} z_{0}^{b}<\lambda\right)\left[g_{z_{1}^{a}}^{\max }(i) \leq v<f_{z_{0}^{b}}(i)<w\right. \\
\text { and } \left.\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right] . \tag{4.23}
\end{gather*}
$$

Since both $\kappa$ and $\lambda_{i}$ are less than $\lambda=\operatorname{cf}(\lambda)$, we can move some quantifiers around and achieve

$$
\begin{gather*}
\left(\forall^{*} i<\kappa\right)\left(\forall^{*} w<\lambda_{i}\right)\left(\exists^{*} z_{0}^{a}<\lambda\right)\left(\exists v<\lambda_{i}\right)\left(\exists^{*} z_{1}^{a}<\lambda\right) \\
\left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\exists^{*} z_{0}^{b}<\lambda\right)\left[g_{z_{1}^{a}}^{\max }(i) \leq v<f_{z_{0}^{b}}(i)<w\right. \\
\text { and } \left.\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right] . \tag{4.24}
\end{gather*}
$$

Thus there is a function $h \in \prod_{i<\kappa} \lambda_{i}$ such that

$$
\begin{align*}
& \left(\forall^{*} i<\kappa\right)\left(\exists^{*} z_{0}^{a}<\lambda\right)\left(\exists v<\lambda_{i}\right)\left(\exists^{*} z_{1}^{a}<\lambda\right) \\
& \left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\exists^{*} z_{0}^{b}<\lambda\right)\left[g_{z_{1}^{a}}^{\max }(i) \leq v<f_{z_{0}^{b}}(i)<h(i)\right. \\
& \left.\quad \text { and }\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i, \beta^{a}, z_{1}^{a}, y_{n}^{b}, z_{0}^{b}, z_{1}^{b}\right)\right]\right] . \tag{4.25}
\end{align*}
$$

After all this work, it is finally time to prove that we can select objects $\beta^{a}<$ $\delta^{a}<\xi_{n}^{b}<\beta^{b}<\delta^{b}$ that satisfy all of our requirements.

Clearly, for every unbounded $\Lambda \subseteq \lambda$,

$$
(\exists i<\kappa)\left(\exists^{*} x \in \Lambda\right)\left(h \upharpoonright[i, \kappa)<f_{x} \upharpoonright[i, \kappa) .\right.
$$

Thus we can choose $i^{*}<\kappa$ such that $h_{1}^{*}\left(i^{*}\right)=j_{1}$ and $h_{0}^{*}\left(i^{*}\right)=n$, and

$$
\begin{aligned}
& \left(\exists^{*} z_{0}^{a}<\lambda\right)\left[h \upharpoonright\left[i^{*}, \kappa\right)<f^{z_{0}^{a}} \upharpoonright\left[i^{*}, \kappa\right) \text { and }\left(\exists v<\lambda_{i}\right)\left(\exists^{*} z_{1}^{a}<\lambda\right)\left(\exists^{*} y_{n}^{b}<\lambda\right)\right. \\
& \left(\exists^{*} z_{0}^{b}<\lambda\right)\left[g_{z_{1}^{a}}^{\max }\left(i^{*}\right) \leq v<f_{z_{0}^{b}}\left(i^{*}\right)<h\left(i^{*}\right)\right. \text { and } \\
& \left.\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i^{*}, z_{0}^{a}, \ldots, z_{1}^{b}\right)\right]\right] .
\end{aligned}
$$

So now we choose $\beta^{a}$ such that $h\left(i^{*}\right)<f_{\beta^{a}}\left(i^{*}\right)$ and for some $\alpha<\lambda_{i^{*}}$,

$$
\begin{aligned}
& \left(\exists^{*} z_{1}^{a}<\lambda\right)\left(\exists^{*} y_{n}^{b}<\lambda\right)\left(\exists^{*} z_{0}^{b}<\lambda\right)\left[g_{z_{1}^{a}}^{\max }\left(i^{*}\right) \leq \alpha<f_{z_{0}^{b}}\left(i^{*}\right)<h\left(i^{*}\right)\right. \text { and } \\
& \left.\left(\exists^{*} z_{1}^{b}<\lambda\right)\left[\Phi\left(i^{*}, z_{0}^{a}, \ldots, z_{1}^{b}\right)\right]\right] .
\end{aligned}
$$

Now we choose $\delta^{a}, \xi_{n}^{b}, \beta^{b}$, and $\delta^{b}$ such that

- $\beta^{a}<\delta^{a}<\xi_{n}^{b}<\beta^{b}$
- $g_{\delta^{a}}^{\max }\left(i^{*}\right) \leq \alpha<f_{\beta^{b}}\left(i^{*}\right)<h\left(i^{*}\right)<f_{\beta^{a}}\left(i^{*}\right)$
- $\Phi\left(i^{*}, \beta^{a}, \delta^{a}, \xi_{n}^{b}, \beta^{b}, \delta^{b}\right)$

It is straightforward to check that these objects satisfy all the requirements listed in Table 1, so by Claim 3.5, we are done.

## 5. Conclusions

In this final section, we will deduce some conclusions in a few concrete cases.
Theorem 2. If $\mu$ is a singular cardinal of uncountable cofinality that is not a limit of regular Jonsson cardinals, then $\operatorname{Pr}_{1}\left(\mu^{+}, \mu^{+}, \mu^{+}, \operatorname{cf}(\mu)\right)$ holds.

Proof. The proof of this theorem occurs in two stages-we first show that $\operatorname{Pr}_{1}\left(\mu^{+}, \mu^{+}, \mu, \operatorname{cf}(\mu)\right)$ holds, and then we show that this result can be upgraded to obtain $\operatorname{Pr}_{1}\left(\mu^{+}, \mu^{+}, \mu^{+}, \operatorname{cf}(\mu)\right.$.

Let $\mu$ be as hypothesized, and let us define $\lambda=\mu^{+}$and $\kappa=\operatorname{cf}(\mu)$.
Claim 5.1. $\operatorname{Pr}_{1}(\lambda, \lambda, \mu, \kappa)$ holds.
Proof. Let $\left\langle\kappa_{i}: i<\kappa\right\rangle$ be a strictly increasing continuous sequence cofinal in $\mu$. Let $S \subseteq\{\delta \in[\mu, \lambda): \operatorname{cf}(\delta)=\kappa\}$ be stationary. Standard club-guessing results tell us that there is an $S$-club system $\bar{C}$ such that $\operatorname{id}_{p}(\bar{C}, \bar{J})$ is a proper ideal, where $J_{\delta}$ is the ideal $J_{C_{\delta}}^{b[\mu]}$ for $\delta \in S$, and furthermore, satisfying $\left|C_{\delta}\right|=\kappa$. (Note that this last requires that $\kappa=\operatorname{cf}(\mu)$ is uncountable.)

At this point, we have satisfied all of the assumptions of Claim 2.2 except possibly for clause (8). It suffices to show that for each $i<\kappa$, for all sufficiently large regular $\theta<\mu$, Player I has a winning strategy in the game $\operatorname{Gm}^{\omega}\left[\theta, \kappa_{i}, 1\right]$. Since $\mu$ is not a limit of regular Jonsson cardinals, it follows that for all sufficiently large regular $\theta<\mu$, Player I has a winning strategy in $\operatorname{Gm}^{\omega}[\theta, \theta, 1]$. This implies, by Lemma 1.3 (1), that for all sufficiently large regular $\theta$, Player I has a winning strategy in $\operatorname{Gm}^{\omega}\left[\theta, \kappa_{i}, 1\right]$, and so clause (8) of Claim 2.2 is satisfied.

To finish the proof of Theorem 2, it remains to show that we can increase the number of colors from $\mu$ to $\lambda=\mu^{+}-$we need $\operatorname{Pr}_{1}(\lambda, \lambda, \lambda, \kappa)$ instead of $\operatorname{Pr}_{1}(\lambda, \lambda, \mu, \kappa)$.

Lemma 5.2. There is a coloring $c_{1}:[\lambda]^{2} \rightarrow \lambda$ such that whenever we are given

- $\theta<\kappa$,
- $\left\langle t_{\alpha}: \alpha<\lambda\right\rangle$ a sequence of pairwise disjoint elements of $[\lambda]^{\theta}$,
- $\zeta_{\alpha} \in t_{\alpha}$ for $\alpha<\lambda$, and
- $\Upsilon<\lambda$,
we can find $\alpha<\beta$ such that $t_{\alpha} \subseteq \min \left(t_{\beta}\right)$ and

$$
\begin{equation*}
\left(\forall \zeta \in t_{\alpha}\right)\left[c_{1}\left(\zeta, \zeta_{\beta}\right)=\Upsilon\right] . \tag{5.1}
\end{equation*}
$$

Proof. Let $c:[\lambda]^{2} \rightarrow \mu$ be a coloring that witnesses $\operatorname{Pr}_{1}(\lambda, \lambda, \mu, \kappa)$. For each $\alpha<\lambda$, let $g_{\alpha}$ be a one-to-one function from $\alpha$ into $\mu$. We define

$$
\begin{equation*}
c_{1}(\alpha, \beta)=g_{\beta}^{-1}(c(\alpha, \beta)) . \tag{5.2}
\end{equation*}
$$

Suppose now that we are given objects $\theta,\left\langle t_{\alpha}: \alpha<\lambda\right\rangle,\left\langle\zeta_{\alpha}: \alpha<\lambda\right\rangle$, and $\Upsilon$ as in the statement of the lemma. Clearly we may assume that $\min \left(t_{\alpha}\right)>\alpha$.

For $i<\mu$, we define $X_{i}:=\left\{\alpha \in[\gamma, \lambda): g_{\zeta_{\alpha}}(\Upsilon)=i\right\}$. Since $\lambda$ is a regular cardinal, it is clear that there is $i^{*}<\mu$ for which $\left|X_{i^{*}}\right|=\lambda$. Since $c$ exemplifies $\operatorname{Pr}_{1}(\lambda, \lambda, \mu, \kappa)$, for some $\alpha<\beta$ in $X_{i^{*}}$ we have $t_{\alpha} \subseteq \min \left(t_{\beta}\right)$ and

$$
\begin{equation*}
\left(\forall \zeta \in t_{\alpha}\right)\left[c\left(\zeta, \zeta_{\beta}\right)=i^{*}\right] . \tag{5.3}
\end{equation*}
$$

By definition, this means

$$
\begin{equation*}
(\forall \zeta \in t)\left[c_{1}\left(\zeta, \zeta_{\beta}\right)=g^{-1}(c(\alpha, \beta))=g^{-1}\left(i^{*}\right)=\Upsilon\right] \tag{5.4}
\end{equation*}
$$

hence $\alpha$ and $\beta$ are as required.
To continue the proof of Theorem 2, we define a coloring $c_{2}:[\lambda]^{2} \rightarrow \lambda$ by

$$
\begin{equation*}
c_{2}(\alpha, \beta)=c_{1}(\alpha, \nu(\alpha, \beta)), \tag{5.5}
\end{equation*}
$$

where $v(\alpha, \beta)$ is as in the proof of Theorem 1 .
It remains to check that $c_{2}$ witnesses $\operatorname{Pr}_{1}(\lambda, \lambda, \lambda, \kappa)$. Toward this end, suppose we are given $\theta<\kappa,\left\langle t_{\alpha}: \alpha<\lambda\right\rangle$ a sequence of pairwise disjoint members of $[\lambda]^{\theta}$, and $\Upsilon<\lambda$. We need to find $\delta^{a}$ and $\delta^{b}$ less than $\lambda$ such that

$$
\begin{equation*}
\epsilon^{a} \in t_{\delta^{a}} \wedge \epsilon^{b} \in t_{\delta^{b}} \Longrightarrow c_{2}\left(\epsilon^{a}, \epsilon^{b}\right)=\Upsilon . \tag{5.6}
\end{equation*}
$$

Lemma 5.3. There is a stationary set of $\gamma_{1}<\lambda$ such that for some $\gamma_{0}<\gamma_{1}$ and $\beta \in\left[\gamma_{1}, \lambda\right)$, if $\gamma_{0} \leq \alpha<\gamma_{1}$, then the function $\nu$ is constant on $t_{\alpha} \times t_{\beta}$.

Proof. Let $E$ be an arbitrary closed unbounded subset of $\lambda$, and let $W$ be the set of ordinals $<\lambda$ satisfying the properties of $\gamma_{1}$. In the proof of Theorem 1 , without loss of generality we can have $E \in M_{0}$. This means that the ordinal $\beta^{*}$ found in the course of that proof will be in $E$, so we finish by observing that $\beta^{*} \in W$.

An application of Fodor's Lemma gives us a single ordinal $\gamma_{0}$ and a stationary $W^{\prime} \subseteq W$ such that for all $\gamma \in W^{\prime}$, there is a $\beta_{\gamma} \in[\gamma, \lambda)$ such that for all $\alpha \in\left[\gamma_{0}, \gamma\right), v \upharpoonright\left(t_{\alpha} \times t_{\beta}\right)$ is constant.

Using properties of the coloring $c_{1}$, we can find $\alpha$ and $\gamma$ such that

- $\gamma_{0} \leq \alpha<\lambda$
- $\gamma \in W^{\prime} \backslash\left(\sup \left(t_{\alpha}\right)+1\right)$, and
$\bullet \zeta \in t_{\alpha} \Longrightarrow c_{1}(\zeta, \gamma)=\Upsilon$.
Now given $\epsilon^{a} \in t_{\alpha}$ and $\epsilon^{b} \in t_{\beta_{\gamma}}$, we find

$$
\begin{equation*}
c_{2}\left(\epsilon^{a}, \epsilon^{b}\right)=c_{1}\left(\epsilon^{a}, \gamma\right)=\Upsilon, \tag{5.7}
\end{equation*}
$$

and therefore $c_{2}$ exemplifies $\operatorname{Pr}(\lambda, \lambda, \lambda, \kappa)$.
Theorem 2 strengthens results in [1] as clearly $\operatorname{Pr}_{1}\left(\mu^{+}, \mu^{+}, \mu^{+}, \operatorname{cf}(\mu)\right)$ implies that $\mu^{+}$has a Jonsson algebra (i.e., $\mu^{+}$is not a Jonsson cardinal). The question of whether the successor of a singular cardinal can be a Jonsson cardinal is a wellknown open question.

We note that many of the results from Section 2 of [1] dealing with the existence of winning strategies for Player I in $\mathrm{Gm}^{\omega}[\lambda, \mu, \gamma]$ can be combined with Theorem 1 to give new results. For example, we have the following result from [1].

Proposition 5.4. If $\tau \leq 2^{\kappa}$ but $(\forall \theta<\kappa)\left[2^{\theta}<\tau\right]$, then Player I has a winning strategy in the game $\mathrm{Gm}^{\omega}\left(\tau, \kappa, \kappa^{+}\right)$.

Proof. See Claim 2.3(1) and Claim 2.4(1) of [1].
Armed with this, the following claim is straightforward.
Claim 5.5. Let $\mu$ be a singular cardinal of uncountable cofinality. Further assume that $\chi$ is a cardinal such that $2^{<\chi} \leq \mu<2^{\chi}$. Then $\operatorname{Pr}_{1}\left(\mu^{+}, \mu^{+}, \chi, \operatorname{cf}(\mu)\right)$ holds.

Proof. If $2<\chi<\mu$, then Claims 2.3(1) and 2.4(1) of [1] imply that for every sufficiently large $\theta<\mu$, Player I has a winning strategy in the game $\operatorname{Gm}^{\omega}\left(\theta, \chi, \chi^{+}\right)$.

If $\mu=2^{<\chi}$, then $\operatorname{cf}(\mu)=\operatorname{cf}(\chi)$. Let $\left\langle\kappa_{i}: i<\operatorname{cf}(\mu)\right\rangle$ be a strictly increasing continuous sequence of cardinals cofinal in $\chi$. Given $i<\operatorname{cf}(\mu)$, we claim that for all sufficiently large regular $\tau<\mu$, Player I has a winning strategy in $\operatorname{Gm}^{\omega}\left(\tau, \kappa_{i}, \chi\right)$. Once we have established this, $\operatorname{Pr}_{1}\left(\mu^{+}, \mu^{+}, \chi, \operatorname{cf}(\mu)\right)$ follows by Theorem 1 .

Given $\tau=\operatorname{cf}(\tau)$ satisfying $2^{\kappa_{i}}<\tau<\mu$, let $\eta$ be the least cardinal such that $\tau \leq 2^{\eta}$. Clearly $\kappa_{i}<\eta<\chi$. By Proposition 5.4, Player I wins the game $\operatorname{Gm}^{\omega}\left(\tau, \eta, \eta^{+}\right)$. This implies (since $\eta^{+}<\chi$ and $\kappa_{i}<\eta$ ) that Player I wins the game $\operatorname{Gm}^{\omega}\left(\tau, \kappa_{i}, \chi\right)$ as required.

We can also use Claim 1.4 to prove similar results. For example we have the following.

Claim 5.6. Let $\mu$ be a singular cardinal of uncountable cofinality. Further assume that $\chi<\mu$ satisfies $2^{\chi}<\mu<\beth_{\left(2^{\chi}\right)^{+}}(\chi)$. Then $\operatorname{Pr}_{1}\left(\mu^{+}, \mu^{+}, \chi, \operatorname{cf}(\mu)\right)$ holds.

Proof. Again, the main point is that for all sufficiently large regular $\theta<\mu$, Player I has a winning strategy in the game $\operatorname{Gm}^{\omega}\left[\theta, \chi,\left(2^{\chi}\right)^{+}\right]$. This follows immediately from Claim 1.4. Since $\left(2^{\chi}\right)^{+}<\mu$, Theorem 1 is applicable.

In a sequel to this paper, we will address the situation where $\lambda$ is the successor of a singular cardinal of countable cofinality. Similar results hold, but the combinatorics involved are trickier.
