ABSTRACT. On the one hand we deal with  $(< \kappa)$ -supported iterated forcing notions which are  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ -complete, have in mind problems on Whitehead groups, uniformizations and the general problem. We deal mainly with the caes of a successor of the singular cardinal. This continues [Sh 587]. On the other hand we deal with complimentary ZFC combinatorial results.

## ANNOTATED CONTENT

- §1 GCH implies for successor of singular no stationary  $S$  has uniformization  
 [For  $\lambda$  strong limit singular, for stationary  $S \subseteq S_{\text{cf}(\lambda)}^{\lambda^+}$  we prove strong negation of uniformization for some  $S$ -ladder system and even weak versions of diamond. E.g. if  $\lambda$  is singular strong limit and  $2^\lambda = \lambda^+$ , then there are  $\gamma_i^\delta < \delta$  increasing in  $i < \text{cf}(\lambda)$  with limit  $\delta$  for each  $\delta \in S$  such that for every  $f : \lambda^+ \rightarrow \alpha^* < \lambda$  for stationarily many  $\delta \in S$ , for every  $i$  we have  $f(\gamma_{2i}^\delta) = f(\gamma_{2i+1}^\delta)$ .]
- §2 Forcing for successor of singulars  
 [Let  $\lambda$  be strong limit singular  $\kappa = \lambda^+ = 2^\lambda, S \subseteq S_{\text{cf}(\lambda)}^\kappa$  stationary not reflecting. We present the consistency of a forcing axiom implying e.g.: if  $h_\delta$  is a function from  $A_\delta$  to  $\theta, A_\delta \subseteq \delta = \sup(A_\delta), \text{otp}(A_\delta) = \text{cf}(\lambda), \theta < \lambda$  then for some  $h : \kappa \rightarrow \theta$  for every  $\delta \in S$  we have  $h_\delta \subseteq^* h$ .]
- §3  $\kappa^+$ -c.c. and  $\kappa^+$ -pic  
 [In the forcing axioms we would like to allow forcing notions of cardinality  $> \kappa$ ; for this we use a suitable chain condition (allowed here and in [Sh 587]). This sheds more light on the strongly inaccessible case and we comment on this (and forcing against cases of diamonds).]
- §4 Existence of non-free Whitehead groups (and  $\text{Ext}(G, \mathbb{Z}) = 0$ ) abelian groups in successor of singulars  
 [We use the information on the existence of weak version of the diamond for  $S \subseteq S_{\text{cf}(\lambda)}^{\lambda^+}, \lambda$  strong limit singular with  $2^\lambda = \lambda^+$ , to prove that there are some abelian groups with special properties (from reasonable assumptions). We also get more combinatorial principles on  $\lambda = \mu^+, \mu > \text{cf}(\mu)$  (even if just  $\lambda = \lambda^{2^\sigma}$ ).]

§1 GCH IMPLIES FOR SUCCESSOR OF SINGULAR  
NO STATIONARY  $S$  HAS UNIFORMIZATION

We show that a major improvement in [Sh 587] over [Sh 186] for inaccessible (every ladder on  $S$  has uniformization rather than some ladder on  $S$ ) cannot be done for successor of singulars. This is continued in §4.

1.1 Fact: Assume

- (a)  $\lambda$  is strong limit singular with  $2^\lambda = \lambda^+$ , let  $\text{cf}(\lambda) = \sigma$
- (b)  $S \subseteq \{\delta < \lambda^+ : \text{cf}(\delta) = \sigma\}$  is stationary.

Then we can find  $\langle \gamma_i^\delta : i < \sigma \rangle : \delta \in S$  such that

- ( $\alpha$ )  $\gamma_i^\delta$  is increasing (with  $i$ ) with limit  $\delta$
- ( $\beta$ ) if  $\mu < \lambda$  and  $f : \lambda^+ \rightarrow \mu$  then the following set is stationary:  
 $\{\delta \in S : f(\gamma_{2i}^\delta) = f(\gamma_{2i+1}^\delta) \text{ for every } i < \sigma\}$ .  
Moreover
- ( $\beta$ )<sup>+</sup> if  $f_i : \lambda^+ \rightarrow \mu_i, \mu_i < \lambda$  for  $i < \sigma$  then the following set is stationary:  
 $\{\delta \in S : f_i(\gamma_{2i}^\delta) = f_i(\gamma_{2i+1}^\delta) \text{ for every } i < \sigma\}$ .

*Proof.* This will prove 1.2, too. We first concentrate on ( $\alpha$ ) + ( $\beta$ ) only.

Let  $\lambda = \sum_{i < \sigma} \lambda_i, \lambda_i$  a cardinal increasing continuous with  $i, \lambda_{i+1} > 2^{\lambda_i}, \lambda_0 > 2^\sigma$ . For

$\alpha < \lambda^+$ , let  $\alpha = \bigcup_{i < \sigma} a_{\alpha, i}$  such that  $|a_{\alpha, i}| \leq \lambda_i$ . Without loss of generality  $\delta \in S \Rightarrow \delta$

divisible by  $\lambda^\omega$  (ordinal exponentiation). For  $\delta \in S$  let  $\langle \beta_i^\delta : i < \sigma \rangle$  be increasing continuous with limit  $\delta, \beta_i^\delta$  divisible by  $\lambda$  and  $> 0$ . For  $\delta \in S$  let  $\langle b_i^\delta : i < \sigma \rangle$  be such that:  $b_i^\delta \subseteq \beta_i^\delta, |b_i^\delta| \leq \lambda_i, b_i^\delta$  is increasing continuous with  $i$  and  $\delta = \bigcup_{i < \sigma} b_i^\delta$  (e.g. we

can let  $b_i^\delta = \bigcup_{j_1, j_2 < i} a_{\beta_{j_1}^\delta, j_2} \cup \lambda_i$ ). We further demand  $\lambda_i \subseteq b_i^\delta \cap \lambda$ . Let  $\langle f_\alpha^* : \alpha < \lambda^+ \rangle$

list the two-place functions with domain an ordinal  $< \lambda^+$  and range  $\subseteq \lambda^+$ . Let  $S = \bigcup_{\mu < \lambda} S_\mu$ , with each  $S_\mu$  stationary and  $\langle S_\mu : \mu < \lambda \rangle$  pairwise disjoint. We now

fix  $\mu < \lambda$  and will choose  $\bar{\gamma}^\delta = \langle \gamma_i^\delta : i < \sigma \rangle$  for  $\delta \in S_\mu$  such that clause ( $\alpha$ ) holds and clause ( $\beta$ ) holds (that is for every  $f : \lambda^+ \rightarrow \mu$  for stationary many  $\delta \in S_\mu$  the conclusion of clause ( $\beta$ ) holds), this clearly suffices.

Now for  $\delta \in S_\mu$  and  $i < j < \sigma$  we can choose  $\zeta_{i, j, \varepsilon}^\delta$  (for  $\varepsilon < \lambda_j$ ) (really here we use just  $\varepsilon = 0, 1$ ) such that:

- (A)  $\langle \zeta_{i,j,\varepsilon}^\delta : \varepsilon < \lambda_j \rangle$  is a strictly increasing sequence of ordinals
- (B)  $\beta_i^\delta < \zeta_{i,j,\varepsilon}^\delta < \beta_{i+1}^\delta$ , (can even demand  $\zeta_{i,j,\varepsilon}^\delta < \beta_i^\delta + \lambda$ )
- (C)  $\zeta_{i,j,\varepsilon}^\delta \notin \{\zeta_{i_1,j_1,\varepsilon_1}^\delta : j_1 < j, \varepsilon_1 < \lambda_{j_1} \text{ (and } i_1 < \sigma, \text{ really only } i_1 = i \text{ matters)}\}$
- (D) for every  $\alpha_1, \alpha_2 \in b_j^\delta$ , the sequence  $\langle \text{Min}\{\lambda_j, f_{\alpha_1}^*(\alpha_2, \zeta_{i,j,\varepsilon}^\delta)\} : \varepsilon < \lambda_j \rangle$  is constant i.e.: one of the following occurs:
  - ( $\alpha$ )  $\varepsilon < \lambda_j \Rightarrow (\alpha_2, \zeta_{i,j,\varepsilon}^\delta) \notin \text{Dom}(f_{\alpha_1}^*)$
  - ( $\beta$ )  $\varepsilon < \lambda_j \Rightarrow f_{\alpha_1}^*(\alpha_2, \zeta_{i,j,\varepsilon}^\delta) = f_{\alpha_1}^*(\alpha_2, \zeta_{i,j,0}^\delta)$ , well defined
  - ( $\gamma$ )  $\varepsilon < \lambda_j \Rightarrow f_{\alpha_1}^*(\alpha_2, \zeta_{i,j,\varepsilon}^\delta) \geq \lambda_j$ , well defined.

For each  $i < j < \sigma$  we use “ $\lambda$  is strong limit  $> \lambda_j \geq \sum_{j_1 < j} \lambda_{j_1} + \sigma$ ”.

Let  $G = \{g : g \text{ a function from } \sigma \text{ to } \sigma \text{ such that } (\forall i < \sigma)(i < g(i))\}$ .

For each function  $g \in G$  we try  $\bar{\gamma}^{g,\delta} = \langle \zeta_{i,g(i),0}^\delta, \zeta_{i,g(i),1}^\delta : i < \sigma \rangle$  i.e.  $\langle \zeta_{2i}^{g,\delta}, \zeta_{2i+1}^{g,\delta} \rangle = \langle \gamma_{i,g(i),0}^\delta, \gamma_{i,g(i),1}^\delta \rangle$ .

Now we ask for each  $g \in G$ :

Question $^\mu$ : Does  $\langle \bar{\gamma}^{g,\delta} : \delta \in S_\mu \rangle$  satisfy

$$(\forall f \in \lambda^+ \mu)(\exists^{\text{stat}} \delta \in S_\mu)(\bigwedge_{i < \sigma} f(\gamma_{2i}^{g,\delta}) = f(\gamma_{2i+1}^{g,\delta}))?.$$

If for some  $g \in G$  the answer is yes, we are done. Assume not, so for each  $g \in G$  we can find  $f_g : \lambda^+ \rightarrow \mu$  and a club  $E_g$  of  $\lambda^+$  such that:

$$\delta \in S_\mu \cap E_g \Rightarrow (\exists i < \sigma)(f_g(\gamma_{2i}^{g,\delta}) \neq f_g(\gamma_{2i+1}^{g,\delta}))$$

which means

$$\delta \in S_\mu \cap E_g \Rightarrow (\exists i < \sigma)[f_g(\zeta_{i,g(i),0}^\delta) \neq f_g(\zeta_{i,g(i),1}^\delta)].$$

Let  $G = \{g_\varepsilon : \varepsilon < 2^\sigma\}$ , so we can find a 2-place function  $f^*$  from  $\lambda^+$  to  $\mu$  satisfying  $f^*(\varepsilon, \alpha) = f_{g_\varepsilon}(\alpha)$  when  $\varepsilon < 2^\sigma, \alpha < \lambda^+$ . Hence for each  $\alpha < \lambda^+$  there is  $\gamma[\alpha] < \lambda^+$  such that  $f^* \upharpoonright \alpha = f_{\gamma[\alpha]}^*$ .

Let  $E^* = \bigcap_{\varepsilon < 2^\sigma} E_{g_\varepsilon} \cap \{\delta < \lambda^+ : \text{for every } \alpha < \delta \text{ we have } \gamma[\alpha] < \delta\}$ . Clearly it is a club of  $\lambda^+$ , hence we can find  $\delta \in S_\mu \cap E^*$ . Now  $\beta_{i+1}^\delta < \delta$  hence  $\gamma[\beta_{i+1}^\delta] < \delta$

(as  $\delta \in E^*$ ) but  $\delta = \bigcup_{i < \sigma} b_i^\delta$  hence for some  $j < \sigma, \gamma[\beta_{i+1}^\delta] \in b_j^\delta$ ; as  $b_j^\delta$  increases with

$j$  we can define a function  $h : \sigma \rightarrow \sigma$  by  $h(i) = \text{Min}\{j : j > i + 1 \text{ and } \mu < \lambda_j \text{ and } \gamma[\beta_{i+1}^\delta] \in b_j^\delta\}$ . So  $h \in G$  hence for some  $\varepsilon(*) < 2^\sigma$  we have  $h = g_{\varepsilon(*)}$ . Now looking at the choice of  $\zeta_{i,h(i),0}^\delta, \zeta_{i,h(i),1}^\delta$  we know (remember  $2^\sigma < \lambda_0 \subseteq b_j^\delta$  and  $\mu < \lambda_{h(i)}$ )

$$(\forall \varepsilon < 2^\sigma)(\forall \alpha \in b_{h(i)}^\delta)[\text{Rang}(f_\alpha^*) \subseteq \mu \ \& \ \text{Dom}(f_\alpha^*) \supseteq \beta_{i+1}^\delta \rightarrow f_\alpha^*(\varepsilon, \zeta_{i,h(i),0}^\delta) = f_\alpha^*(\varepsilon, \zeta_{i,h(i),1}^\delta)].$$

In particular this holds for  $\varepsilon = \varepsilon(*), \alpha = \gamma[\beta_{i+1}^\delta]$ , so we get

$$f_{\gamma[\beta_{i+1}^\delta]}^*(\varepsilon(*), \zeta_{i,h(i),0}^\delta) = f_{\gamma[\beta_{i+1}^\delta]}^*(\varepsilon(*), \zeta_{i,h(i),1}^\delta).$$

By the choice of  $f^*$  and of  $\gamma[\beta_{i+1}^\delta]$  this means

$$f_{g_{\varepsilon(*)}}(\zeta_{i,h(i),0}^\delta) = f_{g_{\varepsilon(*)}}(\zeta_{i,h(i),1}^\delta)$$

but  $h = g_{\varepsilon(*)}$  and the above equality means  $f_{g_{\varepsilon(*)}}^*(\gamma_{2i}^{g_{\varepsilon(*)},\delta}) = f_{g_{\varepsilon(*)}}^*(\gamma_{2i+1}^{g_{\varepsilon(*)},\delta})$ , and this holds for every  $i < \sigma$ , and  $\delta \in E^* \Rightarrow \delta \in E_{g_{\varepsilon(*)}}$  so we get a contradiction to the choice of  $(f_{g_{\varepsilon(*)}}, E_{\varepsilon(*)})$ .

So we have finished proving  $(\alpha) + (\beta)$ .

How do we get  $(\beta)^+$  of 1.1, too?

The first difference is in phrasing the question, now it is, for  $g \in G$ :

Question $_\mu^g$ : Does  $\langle \bar{\gamma}^{g,\delta} : \delta \in S_\mu \rangle$  satisfy:

$$\left( (\forall f_0 \in \lambda^+ \mu_0)(\forall f_1 \in \lambda^+ \mu_1) \dots (\forall f_i \in \lambda^+ \mu_i) \dots \right)_{i < \sigma} (\exists^{\text{stat}} \delta \in S_\mu) \left( \bigwedge_{i < \sigma} f_i(\gamma_{2i}^{g,\delta}) = f_i(\gamma_{2i+1}^{g,\delta}) \right).$$

If for some  $g$  the answer is yes, we are done, so assume not so we have  $f_{g,i} \in \lambda^+(\mu_i)$  for  $g \in G, i < \sigma$  and club  $E_g$  of  $\lambda^+$  such that

$$\delta \in S_\mu \cap E_g \Rightarrow (\exists i < \sigma)(f_{g,i}(\gamma_{2i}^{g,\delta}) \neq f_{g,i}(\gamma_{2i+1}^{g,\delta})).$$

A second difference is the choice of  $f^*$  as  $f^*(\sigma\varepsilon + i, \alpha) = f_{g_\varepsilon,i}(\alpha)$  for  $\varepsilon < 2^\sigma, i < \sigma, \alpha < \lambda^+$ .

Lastly, the equations later change slightly. □<sub>1.1</sub>

**1.2 Fact:** 1) Under the assumptions (a) + (b) of 1.1 letting  $\bar{\lambda} = \langle \lambda_i : i < \sigma \rangle$  be increasingly continuous with limit  $\lambda$  such that  $2^\sigma < \lambda_0, 2^{\lambda_i} < \lambda_{i+1}$  we have  $(*)_1 + (*)_2$  where

$(*)_1$  we can find  $\langle \langle \gamma_\zeta^\delta : \zeta < \lambda \rangle : \delta \in S \rangle$  such that

( $\alpha$ )  $\gamma_\zeta^\delta$  is increasing in  $\zeta$  with limit  $\delta$

( $\beta$ )<sup>+</sup> if  $f_i : \lambda^+ \rightarrow \lambda_{i+1}$ , for  $i < \sigma$ , then the following set is stationary  $\{\delta \in S : f_i(\gamma_\zeta^\delta) = f_i(\gamma_\xi^\delta)$  when  $\zeta, \xi \in [\lambda_i, \lambda_{i+1})$  for every  $i < \sigma\}$

$(*)_2$  moreover if  $F_i : [\lambda^+]^{<\lambda} \rightarrow [\lambda^+]^{\lambda^+}$  for  $i < \sigma$  (or just  $F_i : [\lambda^+]^{<\lambda} \rightarrow [\lambda^+]^\lambda$ ) and  $\sup(w) < \min(F_i(w))$  for  $w \in [\lambda^+]^{<\lambda}$ , for each  $i < \sigma$ , then in addition we can demand

(i)  $\{\gamma_\zeta^\delta : \zeta \in [\lambda_i, \lambda_{i+1}]\} \subseteq F_i(\{\gamma_\zeta^\delta : \zeta < \lambda_i\})$ ,

(ii)  $|\{\langle \gamma_\zeta^\delta : \zeta < \zeta^* \rangle : \gamma_{\zeta^*}^\delta = \gamma\}| \leq \lambda$  for each  $\gamma < \lambda^+$  and  $\zeta^* < \sigma$

2) Assume  $\lambda, \langle \lambda_i : i < \sigma \rangle$  are as in part (1) and  $\langle C_\delta : \delta \in S \rangle$  is given, it guess clubs (for  $\lambda^+$ , which mean that for every club  $E$  of  $\lambda^+$  the set  $\{\delta \in S : C_\delta \subseteq E\}$  is a stationary subset of  $\lambda^+$ ) and  $C_\delta = \{\alpha[\delta, i] : i < \sigma\}$ ,  $\alpha[\delta, i]$  divisible by  $\lambda^\omega$  increasing in  $i$  with limit  $\delta$ ,  $\langle \text{cf}(\alpha[\delta, i+1]) : i < \sigma \rangle$  is increasing with limit  $\lambda$  and let  $\beta(\delta, i) = \sum_{j < i} \lambda_j \times \text{cf}(\alpha[\delta, j])$ . Then

$(*)$  we can find  $\langle \langle \gamma_\zeta^\delta : \zeta < \lambda \rangle : \delta \in S \rangle$  such that

( $\alpha$ )  $\langle \gamma_\zeta^\delta : \zeta < \lambda \rangle$  is increasing with limit  $\delta$ , (for  $\delta \in S$ )

( $\beta$ )  $\sup\{\gamma_\zeta^\delta : \gamma_\zeta^\delta < \beta[\delta, j+1]\} = \alpha[\delta, j]$

( $\gamma$ ) for every  $f_i \in {}^{(\lambda^+)}(\mu_i)$  for  $i < \sigma$  where  $\mu_i < \lambda$  and club  $E$  of  $\lambda^+$ , for stationarily many  $\delta \in S$  we have  $\{\gamma_i^\delta : i < \lambda\} \subseteq E$  and  $f_i(\gamma_\zeta^\delta) = f_i(\gamma_\varepsilon^\delta)$ , when  $\zeta, \varepsilon \in [\beta[\delta, i] + \lambda_i \xi, \beta[\delta, i] + \lambda_i \xi + \lambda_i)$  and  $\xi < \text{cf}(\alpha[\delta, i])$ .

*Proof.* 1) The same proof as in 1.1 for  $(*)_1$ , but see a proof after the proof of 4.2.

2) Should be clear, too.  $\square_{1.2}$

## §2 CASE C: FORCING FOR SUCCESSOR OF SINGULAR

We continue [Sh 587].

*2.1 Hypothesis.* 1)  $\lambda$  strong limit singular  $\sigma = \text{cf}(\lambda) < \lambda, \kappa = \lambda^+, \mu^* \geq \kappa, 2^\lambda = \lambda^+$ .

**2.2 Definition.** 1) Let  $\mathfrak{C}_{<\kappa}(\mu^*)$  be the family of  $\hat{\mathcal{E}}_0 \subseteq \{\bar{a} : \bar{a} = \langle a_i : i \leq \alpha \rangle \text{ where } \alpha < \kappa, a_i \in [\mu^*]^{<\kappa} \text{ increasing continuous, and } a_i \cap \kappa \in \kappa\}$  such that: for every  $\theta = \text{cf}(\theta) < \lambda, \chi$  large enough and  $x \in \mathcal{H}(\chi)$  we can find  $\langle N_i : i \leq \theta \rangle$  obeying  $\bar{a} \in \hat{\mathcal{E}}_0$  (with error some  $n$  see [Sh 587, B.5.1(1)]) and such that  $x \in N_0$ ; this repeats [Sh 587, B.5.1(2)]; formally we should say that  $\bar{N}$  obeys  $\bar{a}$  for  $\mu^*$ .

2)  $\mathfrak{C}_{<\kappa}^1(\mu^*)$  is the family of  $\hat{\mathcal{E}}_1 \subseteq \{\bar{a} : \bar{a} = \langle a_i : i \leq \sigma \rangle, a_i \text{ increasing continuous, } i < \sigma \Rightarrow |a_i| < \lambda \text{ and } \lambda + 1 \subseteq \bigcup_{i < \sigma} a_i\}$ .

**2.3 Definition.** 1) We say  $\bar{M} = \langle M_i : i \leq \sigma \rangle$  is ruled by  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$  if, for some  $\chi > \mu^*$ :

- (a)  $\hat{\mathcal{E}}_0 \in \mathfrak{C}_{<\kappa}(\mu^*), \hat{\mathcal{E}}_1 \in \mathfrak{C}_{<\kappa}^1(\mu^*)$
- (b) for<sup>1</sup> some  $\langle \bar{M}^i : -1 \leq i < \sigma \rangle$  and  $\langle \bar{N}^i : -1 \leq i < \sigma \rangle$  we have:
  - ( $\alpha$ )  $M_i \prec (\mathcal{H}(\chi), \in, <_\chi^*)$
  - ( $\beta$ )  $\bar{M}$  obeys some  $\bar{a} \in \hat{\mathcal{E}}_1$  for some finite error (so for some  $n$ , for every  $i, a_i \subseteq M_i \cap \mu^* \subseteq a_{i+n}$ ) and  $\bar{M} \upharpoonright (i+1) \in M_{i+1}$  and  $j < i \Rightarrow M_j \prec M_i$  and  $M_i$  is increasing continuous
  - ( $\gamma$ )  $[M_{i+1}]^{2^{\|M_i\|}} \subseteq M_{i+1}$  for  $i$  a limit ordinal  $< \sigma$
  - ( $\delta$ )  $\bar{M}^i = \langle M_\alpha^i : \alpha \leq \delta_i \rangle, \bar{N}^i = \langle N_\alpha^i : \alpha \leq \delta_i \rangle$  and  $M_\alpha^i \prec N_\alpha^i \prec (\mathcal{H}(\chi), \in, <_\chi^*)$  and  $\lambda + 1 \subseteq N_\alpha^i$  and  $\|M_\alpha^i\| = \|M_\alpha^i\|^{\|M_i\|}$  for  $\alpha < \delta_i$  non limit,  $[M_\beta^i]^{\|M_i\|} \subseteq M_{\beta+1}^i, \beta < \delta_i$
  - ( $\varepsilon$ )  $\langle N_\alpha^i : \alpha \leq \delta_i \rangle = \bar{N}^i$  obeys some  $\bar{b}_i \in \hat{\mathcal{E}}_0$  for some finite error and  $\bar{M}^i, \bar{N}^i$  are increasing continuous
  - ( $\zeta$ )  $M_{i+1} = M_{\delta_i}^i \subseteq N_{\delta_i}^i$  and  $\langle (\bar{M}^j, \bar{N}^j) : j < i \rangle \in M_0^i$
  - ( $\eta$ )  $\delta_i \subseteq M_{i+1}$  (hence  $\delta_i < \lambda$ ) and  $\lambda \subseteq N_\alpha^i$ ,
  - ( $\theta$ )  $\text{cf}(\delta_i) > 2^{\|M_i\|}$  for  $i$  limit,
  - ( $\iota$ )  $\bar{N}^i \upharpoonright (\alpha + 1), \bar{M}^i \upharpoonright (\alpha + 1) \in M_{\alpha+1}^i$  for  $\alpha < \delta_i, i < \sigma$  hence  $N_\beta^i = \text{Sk}_{(\mathcal{H}(\chi), \in, <_\chi^*)}(M_\beta^i \cup \lambda)$  when  $i < \omega\sigma$  and  $\beta \leq \delta_i$  is a limit ordinal

<sup>1</sup>we may later ignore the  $i = -1$  in our notation

- ( $\kappa$ )  $N_{\delta_i}^i \prec N_0^j$  for  $i < j$
- ( $\lambda$ )  $M_i \prec M_0^i, M_i \in M_0^i$ .

2) We say above that  $(\langle \bar{M}^i : i < \sigma \rangle, \langle \bar{N}^i : i < \sigma \rangle)$  is an  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ -approximation to  $\bar{M}$ .

3) Let  $\mathfrak{C}_{<\kappa}^\spadesuit(\mu^*)$  be the family of  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$  such that:

- (a)  $\hat{\mathcal{E}}_0 \in \mathfrak{C}_{<\kappa}(\mu^*)$  and  $\hat{\mathcal{E}}_1 \in \mathfrak{C}_{<\kappa}^1(\mu^*)$
- (b) for  $\chi$  large enough and  $x \in \mathcal{H}(\chi)$  we can find  $\bar{M}$  which is ruled by  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$  and  $x \in M_0$
- (c)  $\hat{\mathcal{E}}_0$  is closed (see below).

4)  $\hat{\mathcal{E}}_0$  is closed if  $\langle a_i : i \leq \alpha \rangle \in \hat{\mathcal{E}}_0, \gamma \leq \beta \leq \alpha$  implies  $\langle a_i : i \in [\beta, \gamma] \rangle \in \hat{\mathcal{E}}_0$ .

*Remark.* 1) In Definition 2.3(1), letting  $\bar{N} = \bar{N}^0 \wedge \bar{N}^1 \dots$  i.e.  $\bar{N} = \langle N_i : i < \lambda \rangle, N_\varepsilon =: N_\alpha^i$  if  $\varepsilon = \sum_{j < i} \delta_j + \alpha$ ; so  $lg(\bar{N}) = \lambda$  and  $\bar{N} \upharpoonright (i_0 + 1) \in N_{i_0+1}$  so  $\bar{N}$  is  $\prec$ -increasingly continuous, and  $\gamma < \lambda \Rightarrow \bar{N} \upharpoonright \gamma \in N_{\gamma+1}$ .

**2.4 Claim.** 1) Assume  $\hat{\mathcal{E}}_0 \in \mathfrak{C}_{<\kappa}(\mu^*)$  and  $\bar{\mathbb{Q}} = \langle \mathbb{P}_\alpha, \mathbb{Q}_i : i < \gamma \rangle$  is a  $(< \kappa)$ -support iteration such that  $\Vdash_{\mathbb{P}_i} \text{“}\mathbb{Q}_i \text{ is strongly } \hat{\mathcal{E}}_0\text{-complete”}$  for each  $i < \gamma$ , see [Sh 587, B.5.3(3)].

Then  $\mathbb{P}_\gamma$  is strongly  $\hat{\mathcal{E}}_0$ -complete (hence  $\mathbb{P}_\gamma/\mathbb{P}_\beta$ ).

2) If  $\mathbb{Q}$  is  $\hat{\mathcal{E}}_0$ -complete, then  $\mathbf{V}^\mathbb{Q} \models \hat{\mathcal{E}}_0$  non-trivial.

*Proof.* By [Sh 587, B.5.6] (here the choice “for any regular cardinal  $\theta < \kappa$ ” rather than “for any cardinal  $\theta < \kappa$ ” in [Sh 587, B.5.1(2)] is important).  $\square_{2.4}$

**2.5 Definition.** Let  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1) \in \mathfrak{C}_{<\kappa}^\spadesuit(\mu^*)$  and let  $\mathbb{Q}$  be a forcing notion.

1) For a sequence  $\bar{M} = \langle M_i : i \leq \sigma \rangle$  ruled by  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$  with an  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ -approximation  $(\langle \bar{M}^i : i < \sigma \rangle, \langle \bar{N}^i : i < \sigma \rangle)$  and a condition  $r \in \mathbb{Q}$  we define a game  $\mathfrak{G}_{\bar{M}, \langle \bar{M}^i : i < \sigma \rangle, \langle \bar{N}^i : i < \sigma \rangle}^\spadesuit(\mathbb{Q}, r)$  between two players COM and INC.

The play lasts  $\sigma$  moves during which the players construct a sequence  $\langle i_0, p, \langle p_i, \bar{q}_i : i_0 - 1 \leq i < \sigma \rangle \rangle$  such that  $i_0 < \sigma$  is non-limit,  $p \in M_{i_0} \cap \mathbb{Q}, p_i \in M_{i+1} \cap \mathbb{Q}, \bar{q}_i = \langle q_{i,\varepsilon} : \varepsilon < \delta_i \rangle \subseteq \mathbb{Q}$  (where  $\delta_i + 1 = lg(\bar{N}^i)$ ).

The player INC first decides what is  $i_0 < \delta$  and then it chooses a condition  $p \in \mathbb{Q} \cap M_{i_0}$  stronger than  $r$ . Next, at the stage  $i \in [i_0 - 1, \delta)$  of the game, COM chooses  $p_i \in \hat{\mathbb{Q}} \cap M_{i+1}$  such that:

- (i)  $p \leq_{\mathbb{Q}} p_i$
- (ii)  $(\forall j < i)(\forall \varepsilon < \delta_j)(q_{j,\varepsilon} \leq_{\mathbb{Q}} p_i)$ ,
- (iii) if  $i$  is a non-limit ordinal, then  $p_i \in \hat{\mathbb{Q}}$  is minimal satisfying (i) + (ii)
- (iv) if  $i$  is a limit ordinal, then  $p_i \in \mathbb{Q}$ .

Now the player INC answers choosing an increasing sequence  $\bar{q}_i = \langle q_{i,\varepsilon} : \varepsilon < \delta_i \rangle$  such that  $p_i \leq_{\mathbb{Q}} q_{i,0}$  and  $\bar{q}_i$  is  $(\bar{N}^i \upharpoonright [\alpha, \delta_i], \mathbb{Q})^*$ -generic for some  $\alpha < \delta_i$  (see [Sh 587, B.5.3.1]) and  $\beta < \delta_i \Rightarrow \bar{q}_i \upharpoonright (\beta + 1) \in M_{i,\beta+1}$ .

The player COM wins if it has always legal moves and the sequence  $\langle p_i : i < \omega\sigma \rangle$  has an upper bound in  $\mathbb{Q}$ .

2) We say that the forcing notion  $\mathbb{Q}$  is complete for  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$  or  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ -complete if

- (a)  $\mathbb{Q}$  is strongly complete for  $\hat{\mathcal{E}}_0$  and
- (b) for a large enough regular  $\chi$ , for some  $x \in \mathcal{H}(\chi)$ , for every sequence  $\bar{M}$  ruled by  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$  with an  $\hat{\mathcal{E}}_0$ -approximation  $(\langle \bar{M}^i : i < \sigma \rangle, \langle \bar{N}^i : i < \sigma \rangle)$  and such that  $x \in M_0$  and for any condition  $r \in \mathbb{Q} \cap M_0$ , the player INC does not have a winning strategy in the game  $\mathfrak{G}_{\bar{M}, \langle \bar{M}^i : i < \sigma \rangle, \langle \bar{N}^i : i < \sigma \rangle}^{\spadesuit}(\mathbb{Q}, r)$ .

*2.6 Proposition.* Assume

- (a)  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1) \in \mathfrak{C}_{<\kappa}^{\spadesuit}(\mu^*)$ ,
- (b)  $\mathbb{Q}$  is a forcing notion for  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ .

Then  $\Vdash_{\mathbb{Q}} “(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1) \in \mathfrak{C}_{<\kappa}^{\spadesuit}(\mu^*)”$ .

*Proof.* Straightforward (and not used in this paper).

*2.7 Proposition.* Assume that  $\hat{\mathcal{E}} \in \mathfrak{C}_{<\kappa}(\mu^*)$  is closed and  $\bar{\mathbb{Q}} = \langle \mathbb{P}_\alpha, \mathbb{Q}_\alpha : \alpha < \gamma \rangle$  is a  $(< \kappa)$ -support iteration of forcing notions which are strongly complete for  $\hat{\mathcal{E}}$ . Let  $\mathcal{T} = (T, <^+ M, \text{rk})$  be a standard  $(w, \alpha_0)^\gamma$ -tree (see [Sh 587, A.3.3]),  $\|T\| < \lambda$ ,  $w \subseteq \gamma, \alpha_0$  an ordinal, and let  $\bar{p} = \langle p_t : t \in T \rangle \in \text{FTR}'(\bar{\mathbb{Q}})$ , see [Sh 587, A.3.2]. Suppose that  $\mathcal{T}$  is an open dense subset of  $\mathbb{P}_\gamma$ . Then there is  $\bar{q} = \langle q_t : t \in T \rangle \in \text{FTR}'(\bar{\mathbb{Q}})$  such that  $\bar{p} \leq \bar{q}$  and for each  $t \in T$

- (a)  $q_t \in \{q \upharpoonright \text{rk}(t) : q \in \mathcal{I}\}$ , and
- (b) for each  $\alpha \in \text{Dom}(q_t)$ , one of the following occurs:
  - (i)  $q_t(\alpha) = p_t(\alpha)$
  - (ii)  $\Vdash_{\mathbb{P}_\alpha} "q_t(\alpha) \in \underline{\mathbb{Q}}_\alpha"$  (not just in the completion  $\hat{\mathbb{Q}}_\alpha$ )
  - (iii)  $\Vdash_{\mathbb{P}_\alpha}$  "there is  $r \in \underline{\mathbb{Q}}_\alpha$  such that  $\hat{\mathbb{Q}}_\alpha \models p_t(\alpha) \leq r \leq q_t(\alpha)$ " (not really needed).

*Proof.* Just like the proof of [Sh 587, B.7.1].

Our next proposition corresponds to [Sh 587, B.7.2] which corresponds to [Sh 587, A.3.6]. The difference with [Sh 587, B.7.2] is the appearance of the  $\bar{M}, \bar{M}^i$ .

*2.8 Proposition.* Assume that  $\hat{\mathcal{E}} \in \mathfrak{C}_{<\kappa}(\mu^*)$  is closed and  $\bar{\mathbb{Q}} = \langle \mathbb{P}_\alpha, \underline{\mathbb{Q}}_\alpha : \alpha < \gamma \rangle$  is a ( $< \kappa$ )-support iteration and  $x = \langle x_\alpha : \alpha < \gamma \rangle$  is such that

$$\Vdash_{\mathbb{P}_\alpha} "\underline{\mathbb{Q}}_\alpha \text{ is strongly complete for } \hat{\mathcal{E}} \text{ with witness } x_\alpha"$$

(for  $\alpha < \gamma$ ). Further suppose that

- ( $\alpha$ )  $(\bar{N}, \bar{a})$  is an  $\hat{\mathcal{E}}$ -complementary pair (see [Sh 587, B.5.1]),  $\bar{N} = \langle N_i : i \leq \delta \rangle$  and  $x, \hat{\mathcal{E}}, \bar{\mathbb{Q}} \in N_0$ ,
- ( $\beta$ )  $\mathcal{T} = (T, <^+, \text{rk}) \in N_0$  is a standard  $(w, \alpha_0)^\gamma$ -tree,  $w \subseteq \gamma \cap N_0, \|w\| < \text{cf}(\delta), \alpha_0$  is an ordinal,  $\alpha_1 = \alpha_0 + 1$  and  $0 \in w$
- ( $\gamma$ )  $\bar{p} = \langle p_t : t \in T \rangle \in \text{FTr}'(\bar{\mathbb{Q}}) \cap N_0, w \in N_0$ , (of course  $\alpha_0 \in N_0$ , on  $\text{FTr}'$  see [Sh 587, A.3.2]),
- ( $\delta$ )  $\bar{M} = \langle M_i : i \leq \delta \rangle, M_i \prec (\mathcal{H}(\chi), \in, <_\chi^*), M_i$  is increasing continuous,  $[M_i]^{\|w\| + |\mathcal{T}|} \subseteq M_{i+1}$  and the pair  $(\bar{M} \upharpoonright (i+1), \bar{N} \upharpoonright (i+1))$  belongs to  $M_{i+1}, M_i \prec N_i$  and  $w \cup \{x, \hat{\mathcal{E}}_0, \bar{\mathbb{Q}}\} \in M_0$
- ( $\varepsilon$ ) for  $i \leq \delta, \mathcal{T}_i = (T_i, <_i, \text{rk}_i)$  is such that  $T_i$  consists of all sequences  $t = \langle t_\zeta : \zeta \in \text{dom}(t) \rangle$  such that  $\text{dom}(t)$  is an initial segment of  $w$ , and
  - (i) each  $t_\zeta$  is a sequence of length  $\alpha_1$
  - (ii)  $\langle t_\zeta \upharpoonright \alpha_0 : \zeta \in \text{dom}(t) \rangle \in T$
  - (iii) for each  $\zeta \in \text{dom}(t)$ , either  $t_\zeta(\alpha_0) = *$  or  $t_\zeta(\alpha_0) \in M_i$  is a  $\mathbb{P}_\zeta$ -name for an element of  $\underline{\mathbb{Q}}_\zeta$  and  
if  $t_\zeta(\alpha) \neq *$  for some  $\alpha < \alpha_0$ , then  $t_\zeta(\alpha_0) \neq *$ ,

(iv)  $\text{rk}_i(t) = \min(w \cup \{\zeta\} \setminus \text{dom}(t))$  and  $<_i$  is the extension relation.

Then

(a) each  $\mathcal{T}_i$  is a standard  $(w, \alpha_1)^\gamma$ -tree,  $\|T_i\| \leq \|T\| \cdot \|M_i\|^{\|w\|}$  and if  $i < \delta$  then  $T_i \in N_{i+1}$

(b)  $\mathcal{T}$  is the projection of each  $\mathcal{T}_i$  onto  $(w, \alpha_0)$  and  $\mathcal{T}_i$  is increasing with  $i$

(c) there is  $\bar{q} = \langle q_t : t \in T_\delta \rangle \in \text{FTr}'(\bar{\mathbb{Q}})$  such that

(i)  $\bar{p} \leq_{\text{proj}_T^{T_\delta}} \bar{q}$

(ii) if  $t \in T_\delta \setminus \{\langle \rangle\}$  then the condition  $q_t \in \mathbb{P}'_{\text{rk}_\delta(t)}$  is an upper bound of an  $(\bar{N} \upharpoonright [i_0, \delta], \mathbb{P}_{\text{rk}_\delta(t)})^*$ -generic sequence (where  $i_0 < \delta$  is such that  $t \in T_{i_0}$ ) and for every  $\beta \in \text{dom}(q_t) = N_\delta \cap \text{rk}(t)$ ,  $q_t(\beta)$  is a name for the least upper bound in  $\hat{\mathbb{Q}}_\beta$  of an  $(\bar{N}[G_\beta] \upharpoonright [\xi, \delta], \mathbb{Q}_\beta)^*$ -generic sequence (for some  $\xi < \delta$ ).

[Note that by [Sh 587, B.5.5], the first part of the demand on  $q_t$  implies that if  $i_0 \leq \xi$  then  $q_t \upharpoonright \beta$  forces that  $(\bar{N}[G_\beta] \upharpoonright [\xi, \delta], \bar{a} \upharpoonright [\xi, \delta])$  is an  $\hat{\mathcal{S}}$ -complementary pair.]

(iii) if  $t \in T_\delta, t' = \text{proj}_T^{T_\delta}(t) \in T, \zeta \in \text{dom}(t)$  and  $t_\zeta(\alpha_0) \neq *$ , then  $q_t \upharpoonright \zeta \Vdash_{\mathbb{P}_\zeta} "p_{t'}(\zeta) \leq_{\hat{\mathbb{Q}}_\zeta} t_\zeta(\alpha_0) \Rightarrow t_\zeta(\alpha_0) \leq_{\hat{\mathbb{Q}}_\zeta} q_t(\zeta)"$ ,

(iv)  $q_{\langle \rangle} = p_{\langle \rangle}$ .

*Proof.* Clauses (a) and (b) should be clear. Clause (c) is proved as in [Sh 587, B.7.2]. □<sub>2.8</sub>

*Remark.* In 2.9 below is proved as in the inaccessible case i.e. the proofs of ([Sh 587, B.7.3]) with  $\bar{M}, \langle \bar{N}^i : i < \sigma \rangle$  as in Definition 2.5. We define the trees point: in stage  $i$  using trees  $\mathcal{T}_i$  with set of levels  $w_i = M_i \cap \gamma$  and looking at all possible moves of COM, i.e.  $p_i \in M_{i+1} \cap \mathbb{P}_\gamma$ , so constructing this tree of conditions in  $\delta_i$  stages, in stage  $\varepsilon < \delta_i$ , has  $|N_\varepsilon^i \cap M_{i+1}|^{2^{\|M_i\|}}$  nodes.

Now

$$\begin{aligned} p \in \mathbb{P}_\gamma \cap M_{i+1} &\not\Rightarrow \text{Dom}(p) \subseteq M_{i+1} \text{ but} \\ p \in \mathbb{P}_\gamma \cap M_{i+1} &\Rightarrow \text{Dom}(p) \subseteq M_\sigma = \bigcup_{i < \omega\sigma} N_{\delta_i}^i \\ p \in \mathbb{P}_\gamma \cap N_\varepsilon^i &\Rightarrow \text{Dom}(p) \subseteq N_\varepsilon^i. \end{aligned}$$

So in limit cases  $i < \sigma$ : the existence of limit is by the clause  $(\mu)$  of Definition 2.3. In the end we use the winning of the play and then need to find a branch in the tree of conditions of level  $\sigma$ : like Case A using  $\hat{\mathcal{E}}_0$ .  $\square_{2.9}$

**2.9 Theorem.** *Suppose that  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1) \in \mathfrak{C}_{<\kappa}^\spadesuit(\mu^*)$  (so  $\hat{\mathcal{E}}_0 \in \mathfrak{C}_{<\kappa}(\mu^*)$ ) and  $\bar{\mathbb{Q}} = \langle \mathbb{P}_\alpha, \mathbb{Q}_\alpha : \alpha < \gamma \rangle$  is a  $(< \kappa)$ -support iteration such that for each  $\alpha < \kappa$*

$$\Vdash_{\mathbb{P}_\alpha} \text{“}\mathbb{Q}_\alpha \text{ is complete for } (\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)\text{”}.$$

Then

- (a)  $\Vdash_{\mathbb{P}_\gamma} (\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1) \in \mathfrak{C}_{<\kappa}^\spadesuit(\mu^*)$ , moreover
- (b)  $\mathbb{P}_\gamma$  is complete for  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ .

*Proof.* We need only part (a) of the conclusion, so we concentrate on it. Let  $\chi$  be a regular large enough regular cardinal,  $\underline{x}$  be a name for an element of  $\mathcal{H}(\chi)$  and  $p \in \mathbb{P}_\gamma$ . Let  $\underline{x}_\alpha \in \mathcal{H}(\chi)$  be a  $\mathbb{P}_\alpha$ -name for the witness that  $\mathbb{Q}_\alpha$  is (forced to be) complete for  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$  and let  $\bar{x} = \langle \underline{x}_\alpha : \alpha < \gamma \rangle$ . Since  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1) \in \mathfrak{C}_{<\kappa}^\spadesuit(\mu^*)$ , we find  $\bar{M} = \langle M_i : i \leq \sigma \rangle$  which is ruled by  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$  with an  $\hat{\mathcal{E}}_0$ -approximation  $\langle \bar{M}^i, \bar{N}^i : -1 \leq i < \sigma \rangle$  and such that  $p, \bar{\mathbb{Q}}, \underline{x}, \bar{x}, \hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1 \in M_0$  (see 2.3). Let  $\bar{N}^i = \langle N_\varepsilon^i : \varepsilon \leq \delta_i \rangle$  and let  $\bar{a}^i \in \hat{\mathcal{E}}_0$  be such that  $(\bar{N}^i, \bar{a}^i)$  is an  $\hat{\mathcal{E}}_0$ -complementary pair and let  $\bar{M}^i = \langle M_\varepsilon^i : \varepsilon \leq \delta_i \rangle$ . Let  $w_i = \{0\} \cup \bigcup_{\omega j \leq i} (\gamma \cap M_{\omega j})$  (for  $i \leq \delta$ ). By the demands of 2.3 we know that  $\|w_i\| < \text{cf}(\delta_i), w_i \in M_i^i$ .

By induction on  $i \leq \sigma$  we define standard  $(w_i, i)^\gamma$ -trees  $\mathcal{T}_i \in M_{i+1}$  and  $\bar{p}^i = \langle p_t^i : t \in T_i \rangle \in \text{FTr}'(\bar{\mathbb{Q}}) \cap M_{i+1}$  such that  $\|T_i\| \leq \|M_i\|^{\|w_i\|} \leq \|M_{i+1}\|$  if  $i$  is limit or 0,  $w_{i+1} = w_i$  hence  $\mathcal{T}_{i+1} = \mathcal{T}_i$ , and if  $j < i \leq \delta$  then  $\mathcal{T}_j = \text{proj}_{(w_j, j+1)}^{(w_i, i+1)}(\mathcal{T}_i)$  and  $\bar{p}^j \leq_{\text{proj}_{\mathcal{T}_j}^{\mathcal{T}_i}} \bar{p}^i$ .

**CASE 1:**  $i = 0$ .

Let  $T_0^*$  consist of all sequences  $\langle t_\zeta : \zeta \in \text{dom}(t) \rangle$  such that  $\text{dom}(t)$  is an initial segment of  $w_0$  and  $t_\zeta = \langle \rangle$  for  $\zeta \in \text{dom}(t)$ . Thus  $T_0^*$  is a standard  $(w_0, 0)^\gamma$ -tree,  $\|T_0^*\| = \|w_0\| + 1$ . For  $t \in T_0^*$  let  $p_t^{*0} = p \upharpoonright \text{rk}_0^*(t)$ . Clearly the sequence  $\bar{p}^{*0} = \langle p_t^{*0} : t \in T_0^* \rangle$  is in  $\text{FTr}'(\bar{\mathbb{Q}}) \cap N_0^{-1}$ . Apply 2.8 to  $\hat{\mathcal{E}}_0, \bar{\mathbb{Q}}, \bar{N}^{-1}, \mathcal{T}_0^*, w_0$  and  $\bar{p}^{*0}$  (note that  $\|M_\varepsilon^{-1}\|^{\|w_0\|} \subseteq M_\varepsilon^{-1}$  for  $\varepsilon < \delta_0$ ). As a result we get a  $(w_0, 1)^\gamma$ -tree  $\mathcal{T}_0$  (the one called  $\mathcal{T}_{\delta_0}$  there) and  $\bar{p}^0 = \langle p_t^0 : t \in T_0 \rangle \in \text{FTr}'(\bar{\mathbb{Q}}) \cap M_1$  (the one called  $\bar{q}$  there) satisfying

clauses  $(\varepsilon), (c)(i)$ - $(iv)$  of 2.8 and such that  $\|T_0\| \leq \|N_{\delta_0}^{-1}\|^{\|w_0\|} = \|M_0\|^{\|w_0\|} = \|M_0\|$  (remember  $\text{cf}(\delta_0) > 2^{\|M_0\|}$ ). So, in particular, if  $t \in T_0, \zeta \in \text{dom}(t)$  then  $t_\zeta(0) \in M_1$  is either  $*$  of a  $\mathbb{P}_\zeta$ -name for an element of  $\mathbb{Q}_\zeta$ .

Moreover, we additionally require that  $(\mathcal{T}_0, \bar{p}^0)$  is the  $<^*_\chi$ -first with all these properties, so  $\mathcal{T}_0, \bar{p}^0 \in M_1$ .

CASE 2:  $i = i_0 + 1$ .

We proceed similarly to the previous case. Suppose we have defined  $\mathcal{T}_{i_0}$  and  $\bar{p}^{i_0}$  such that  $\mathcal{T}_{i_0}, \bar{p}^{i_0} \in M_{i_0+1}, \|T_{i_0}\| \leq \|M_{i_0+1}\|$ . Let  $\mathcal{T}_i^*$  be a standard  $(w_i, i_0)^\gamma$ -tree such that

$T_i^*$  consists of all sequences  $\langle t_\zeta : \zeta \in \text{dom}(t) \rangle$  such that  $\text{dom}(t)$  is an initial segment of  $w_i$  and

$$\langle t_\zeta : \zeta \in \text{dom}(t) \cap w_{i_0} \rangle \in T_{i_0} \text{ and } (\forall \zeta \in \text{dom}(t) \setminus w_{i_0})(\forall j < i_0)(t_\zeta(j) = *).$$

Thus,  $\mathcal{T}_{i_0} = \text{proj}_{(w_{i_0}, i_0)}^{(w_i, i)}(\mathcal{T}_i^*)$  and  $\|T_i^*\| \leq \|M_i\|$ . Let  $p_t^{*i} = p_{t'}^{i_0} \upharpoonright \text{rk}_i^*(t)$  for  $t \in T_i^*, t' = \text{proj}_{\mathcal{T}_{i_0}}^{\mathcal{T}_i^*}(t)$ . Now apply 2.8 to  $\hat{\mathcal{E}}_0, \bar{\mathbb{Q}}, \bar{N}^{i_0}, \mathcal{T}_i^*, w_i$  and  $\bar{p}^{i_0}$  (check that the assumptions are satisfied). So we get a standard  $(w_i, i_0 + 1)^\gamma$ -tree  $\mathcal{T}_i$  and a sequence  $\bar{p}^i$  satisfying  $(\varepsilon), (c)(i) - (iv)$  of 2.8, and we take the  $<^*_\chi$ -pair  $(\mathcal{T}_i, \bar{p}^i)$  with these properties. In particular, we will have  $\|T_i\| \leq \|M_{i_0}\| \cdot \|N_{\delta_i}^{i_0}\|^{\|M_{i_0}\|} = \|M_{i_0+1}\|$  and  $\bar{p}^i, \mathcal{T}_i \in M_{i_0+1}$ .

CASE 3:  $i$  is a limit ordinal.

Suppose we have defined  $\mathcal{T}_j, \bar{p}^j$  for  $j < i$  and we know that  $\langle (\mathcal{T}_j, \bar{p}^j) : j < i \rangle \in M_{i+1}$  (this is the consequence of taking “the  $<^*_\chi$ -first such that ...”). let  $\mathcal{T}_i^* = \lim(\langle \mathcal{T}_j : j < i \rangle)$ . Now, for  $t \in T_i^*$  we would like to define  $p_t^{*i}$  as the limit of  $p_{\text{proj}_{\mathcal{T}_j}^{\mathcal{T}_i^*}(t)}^j$ . However, our problem is that we do not know if the limit exists.

Therefore, we restrict ourselves to these  $t$  for which the respective sequence has an upper bound. To be more precise, for  $t \in \mathcal{T}_i^*$  we apply the following procedure.

- ⊗ Let  $t^j = \text{proj}_{\mathcal{T}_j}^{\mathcal{T}_i^*}(t)$  for  $j < i$ . Try to define inductively a condition  $p_t^{*i} \in \mathbb{P}_{\text{rk}_i^*(t)}$  such that  $\text{dom}(p_t^{*i}) = \cup\{\text{dom}(p_{t^j}^j) \cap \text{rk}_i^*(t) : j < i\}$ . Suppose we have successfully defined  $p_t^{*i} \upharpoonright \alpha$  for  $\alpha \in \text{dom}(p_t^{*i})$ , in such a way that  $p_t^{*i} \upharpoonright \alpha \geq p_{t^j}^j \upharpoonright \alpha$  for all  $j < i$ . We know that

$$p_t^{*i} \upharpoonright \alpha \Vdash_{\mathbb{P}_\alpha} \text{ “ the sequence } \langle p_{t^j}^j(\alpha) : j < i \rangle \text{ is } \leq_{\hat{\mathbb{Q}}_\alpha} \text{-increasing”}.$$

So now, if there is a  $\mathbb{P}_\alpha$ -name  $\tau$  for an element of  $\mathbb{Q}_\alpha$  such that

$$p_t^{*i} \upharpoonright \alpha \Vdash_{\mathbb{P}_\alpha} “(\forall j < i)(p_{t^j}^j(\alpha) \leq_{\hat{\mathbb{Q}}_\alpha} \tau)”$$

then we take the  $\mathbb{P}_\alpha$ -name of the lub of  $\langle p_{t^j}^j(\alpha) : j < i, p_{t^j}^j(\alpha) \neq * \rangle$  in  $\hat{\mathbb{Q}}$ , and we continue. If there is no such  $\tau$  then we decide that  $t \notin \mathcal{T}_i^+$  and we stop the procedure<sup>2</sup>.

Now, let  $\mathcal{T}_i^+$  consist of those  $t \in T_i^*$  for which the above procedure resulted in a successful definition of  $p_t^{*i} \in \mathbb{P}_{\text{rk}_i^*(t)}$ . It might not be clear at the moment if  $T_i^+$  contains anything more than  $\langle \rangle$ , but we will see that this is the case. Note that

$$\|T_i^+\| \leq \|T_i^*\| \leq \prod_{j < i} \|T_j\| \leq \prod_{j < i} \|M_j\| \leq 2^{\|M_i\|} \leq \|M_0^i\|.$$

Moreover, for nonlimit  $\varepsilon > 2$  we have  $\|M_\varepsilon^i\|^{\|w_i\| + \|T_i^+\|} \leq \|M_\varepsilon^i\|^{\|M_i\|} \subseteq M_{\varepsilon+1}^i$  and  $\mathcal{T}_i^+, \bar{p}^{*i} \in M_{i+1}$ . Let  $\mathcal{T}_i = \mathcal{T}_i^*, \bar{p}^i = \bar{p}^{*i}$  (this time there is no need to take the  $\langle \rangle_\chi^*$ -first pair as the process leaves no freedom). So we have finished Case 3.

After the construction is carried out we continue in a similar manner as in [Sh 587, A.3.7] (but note slightly different meaning of the  $*$ 's here).

So we let  $\mathcal{T}_\sigma = \lim(\langle \mathcal{T}_i : i < \sigma \rangle)$ . It is a standard  $(\sigma, \sigma)^\gamma$ -tree. By induction on  $\alpha \in w_\sigma \cup \{\gamma\}$  we choose  $q_\alpha \in \mathbb{P}'_\alpha$  and a  $\mathbb{P}_\alpha$ -name  $t_\alpha$  such that:

- (a)  $\Vdash_{\mathbb{P}_\alpha} “t_\alpha \in T_{w_\sigma} \ \& \ \text{rk}_\delta(t_\alpha) = \alpha”$  and let  $i_0^\alpha = \min\{i < \delta : \alpha \in M_i\} < \sigma$ ,
- (b)  $\Vdash_{\mathbb{P}_\alpha} “t_\beta = t_\alpha \upharpoonright \beta”$  for  $\beta < \alpha$ ,
- (c)  $\text{dom}(q_\alpha) = w_\delta \cap \alpha$ ,
- (d) if  $\beta < \alpha$  then  $q_\beta = q_\alpha \upharpoonright \beta$ ,
- (e)  $p_{\text{proj}_{\mathcal{T}_i(t_\alpha)}^{\mathcal{T}_\delta}}^i$  is well defined and  $p_{\text{proj}_{\mathcal{T}_i(t_\alpha)}^{\mathcal{T}_\delta}}^i \upharpoonright \alpha \leq q_\alpha$  for each  $i < \omega\sigma$ ,
- (f) for each  $\beta < \alpha$

---

<sup>2</sup>Generally in such situation we can act as in 2.7 to get a real decision, i.e. if  $p_t^{*i} \upharpoonright (\alpha + 1)$  is not well defined while  $p_t^{*i} \upharpoonright \alpha$  is well defined then  $p_t^{*i} \upharpoonright \alpha \Vdash$  “the sequence  $\langle p_{t^j}^j(\alpha) : j < i \rangle$  has no  $\leq_{\hat{\mathbb{Q}}_\alpha}$ -upper bound. But the need has not arisen here.

$q_\alpha \Vdash_{\mathbb{P}_\alpha}$  “ $(\forall i < \delta)((t_{\beta+1})_\beta(i) = * \Leftrightarrow i < i_0^\beta)$  and the sequence

$$\langle i_0^\beta, p_{\text{proj}_{\mathcal{I}_{i_0^\beta}^\beta}^\delta}(t_{\beta+1})^\beta(\beta), \langle (t_{\beta+1})_\beta(i), p_{\text{proj}_{\mathcal{I}_i^\beta}^\delta}(t_{\beta+1})^\beta(\beta) : i_0^\beta \leq i < \delta \rangle \rangle$$

is a result of a play of the game  $\mathfrak{G}_{M[G_\beta], \langle \bar{N}^i[G_\beta] : i < \delta \rangle}^\spadesuit}(\mathbb{Q}_\beta, 0_{\mathbb{Q}_\beta})$ ,

won by player COM”,

- (g) the condition  $q_\alpha$  forces (in  $\mathbb{P}_\alpha$ ) that  
 “the sequence  $\bar{M}[G_{\mathbb{P}_\alpha}] \upharpoonright [i_\alpha, \delta]$  is ruled by  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$  and  
 $\langle \bar{N}^i[G_{\mathbb{P}_\alpha}] : i_0^\alpha \leq i < \sigma \rangle$  is its  $\hat{\mathcal{E}}_0$ -approximation”.

(Remember:  $\hat{\mathcal{E}}_1$  is closed under end segments). This is done completely parallelly to the last part of the proof of [Sh 587, A.3.7].

Finally, look at the condition  $q_\gamma$  and the clause (g) above. □<sub>2.9</sub>

**2.10 Generalization** 1)  $\hat{\mathcal{E}}_1$  is a set of triples  $\langle \bar{a}, \langle \bar{b}^i, \bar{a}^i : i < \sigma \rangle, \bar{\lambda} \rangle$ ,  $\bar{a} = \langle a_i : i \leq \sigma \rangle$ ,  $\bar{a}^i = \langle a_\alpha^i : \alpha \leq \delta_i \rangle$ ,  $\bar{b}^i = \langle b_\alpha^i : \alpha \leq \delta_i \rangle \in \hat{\mathcal{E}}_0$ ,  $a_{\delta_i}^i = a_{i+1}$ ,  $a_i \subseteq b_0^i$ ,  $\lambda = \langle \lambda_i : i < \sigma \rangle$  an increasing sequence of cardinals  $< \lambda$ ,  $\sum \lambda_i = \lambda$ .

2) We say  $(M, \langle M^i : i < \sigma \rangle, \langle \bar{N}^i : i < \sigma \rangle)$  obeys  $(\bar{a}, \langle \bar{b}^i : i < \bar{\lambda} \rangle)$  if:  $M_i \cap \mu^* = a_i$ ,  $\bar{N}^i$  obeys  $\bar{b}^i$  all things in 2.3 but  $\lambda_i \geq \|M_i\|$ ,  $\lambda_i \geq \prod_{j \leq i} \|M_j\|$ ,  $[M_\alpha^i]^{\lambda_i} \subseteq M_{\alpha+1}^i$  for  $\alpha < \delta_i$

(so earlier  $\lambda_i = 2^{\|M_i\|}$ ).

**2.11 Conclusion** 1) Assume

- (a)  $S \subseteq \{\delta < \kappa : \text{cf}(\delta) = \sigma\}$  is stationary not reflecting  
 (b)  $\bar{\mathbf{a}} = \langle \bar{a}_\delta : \delta \in S \rangle$ ,  $\bar{a}_\delta = \langle a_{\delta,i} : i \leq \sigma \rangle$ ,  $\delta = a_{\delta,\sigma}$  and  $a_{\delta,i}$  increasing with  $i$  and  $i < \sigma \Rightarrow |a_{\delta,i}| < \lambda$  and  $\sup(a_{\delta,i}) < \delta$   
 [variant:  $\bar{\lambda}^\delta = \langle \lambda_i^\delta : i < \sigma \rangle$  increasing with limit  $\lambda$ ]  
 (c) we let  $\mu^* = \kappa$ ,  $\hat{\mathcal{E}}_0 = \hat{\mathcal{E}}_0[S] = \{\bar{a} : \bar{a} = \langle a_i : i \leq \alpha \rangle, \alpha < \kappa, a_i \in \kappa \setminus S \text{ increasing continuous}\}$   
 (d)  $\hat{\mathcal{E}}_1 = \{\bar{a}_\delta : \delta \in S\}$   
 (or  $\{\langle \bar{a}_\delta, \langle \bar{a}^{\delta,i}, \bar{b}^{i,\delta} : i < \sigma \rangle, \bar{\lambda}^\delta \rangle : \delta \in S\}$  appropriate for (2.10))  
 (e) we assume the pair  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1) \in \mathfrak{C}_{< \kappa}^\spadesuit}(\mu^*)$   
 (f)  $\mu = \mu^\kappa$ ,  $\kappa < \tau = \text{cf}(\tau) < \mu$ .

Then for some  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ -complete forcing notion  $\mathbb{P}$  of cardinality  $\mu$  we have

$\Vdash_{\mathbb{P}}$  “forcing axiom for  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ -complete forcing notion  
of cardinality  $\leq \kappa$  and  $< \tau$  of open dense sets”

and in  $\mathbf{V}^{\mathbb{P}}$  the set  $S$  is still stationary (by preservation of  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ -nontrivial).

2) If clauses (a),(c) holds and  $\diamond_S$ , then for some  $\bar{a}$ , if we define  $\hat{\mathcal{E}}_1$  as in clause (d) then clause (b),(d),(e) holds.

*Proof.* 1) See more in the end of §3.

2) Easy. □<sub>2.11</sub>

2.12 Application: In  $\mathbf{V}^{\mathbb{P}}$  of 2.11:

(a) if

(i)  $\theta < \lambda, A_\delta \subseteq \delta = \sup(A_\delta)$  for  $\delta \in S$ ,

(ii)  $|A_\delta| < \theta$

(iii)  $\bar{h} = \langle h_\delta : \delta \in S \rangle, h_\delta : A \rightarrow \theta$

(iv)  $A_\delta \subseteq \bigcup \{a_{\delta, i+1} \setminus a_{\delta, i} : i < \sigma\}$ ,

then for some  $h : \kappa \rightarrow \theta$  and club  $E$  of  $\kappa$  we have  $(\forall \delta \in S \cap E)[h_\delta \subseteq^* h]$  where  $h' \subseteq^* h''$  means that  $\sup(\text{Dom}(h')) > \sup\{\alpha : \alpha \in \text{Dom}(h') \text{ and } \alpha \notin \text{Dom}(h'') \text{ or } \alpha \in \text{Dom}(h'') \ \& \ h'(\alpha) \neq h''(\alpha)\}$

(b) if we add: “ $h_\delta$  constant”, then we can omit the assumption (iii)

(c) we can weaken  $|A_\delta| < \theta$  to  $|A_\delta \cap a_{\delta, i+1}| \leq |a_{\delta, i}|$

(d) in (c) we can weaken  $|A_\delta| \leq \theta \vee |A_\delta \cap a_{\delta, i+1}| \leq |a_{\delta, i}|$  to  $h_\delta \upharpoonright a_{\delta, i+1}$  belongs to  $M_{i+1} \cap N_\alpha^i$  for some  $\alpha < \delta_i$  (remember  $\text{cf}(\sup a_{\delta, i+1}) > \lambda_i^\delta$ ).

*2.13 Remark.* 1) Compared to [Sh 186] the new point in the application is (b).

2) You may complain why not having the best of (a) + (b), i.e. combine their good points. The reason is that this is impossible by §1, §4; the situation is different in the inaccessible case.

*Proof.* Should be clear. Still we say something in case  $h_\delta$  constant, that is (b).  
Let

$$\begin{aligned} \mathbb{Q} = \{ & (h, C) : h \text{ is a function with domain an ordinal} \\ & \alpha < \kappa = \lambda^+, \\ & C \text{ a closed subset of } \alpha + 1, \alpha \in C \\ & \text{and } (\forall \delta \in C \cap S \cap (\alpha + 1))(h_\delta \subseteq^* h) \}. \end{aligned}$$

with the partial order being inclusion.

For  $p \in \mathbb{Q}$  let  $p = (h^p, C^p)$ .

So clearly if  $(h, C) \in \mathbb{Q}$  and  $\alpha = \text{Dom}(h) < \beta \in \kappa$  then for some  $h_1$  we have  $h \subseteq h_1 \in \mathbb{Q}_1$ ,  $\text{Dom}(h_1) = \beta$ ; moreover, if  $\gamma < \theta$  &  $\beta \notin S$  then  $(h, C) \leq (h \cup \gamma_{[\alpha, \beta]}, C \cup \{\beta\}) \in \mathbb{Q}$ .

The main point is proving  $\mathbb{Q}$  is complete for  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ . Now “ $\mathbb{Q}$  is strongly complete for  $\hat{\mathcal{E}}_0$ ” is proved as in [Sh 587, B.6.5.1, B.6.5.2] (or 3.14 below which is somewhat less similar). The main point is clause (b) of 2.5(2); that is, let  $\bar{M}, \langle \bar{M}^i : i < \omega\sigma \rangle, \langle \bar{N}^i : i < \omega\sigma \rangle$  be as there. In the game  $\mathfrak{G}_{\bar{M}, \langle \bar{N}^i : i < \omega\sigma \rangle}(r, \mathbb{Q})$  from 2.5(1), we can even prove that the player COM has a winning strategy: in stage  $i$  (non-trivial): if  $h_\delta$  is constantly  $\gamma < \theta$  or just  $h_\delta \upharpoonright (A_\delta \cap a_{\delta, i+1} \setminus a_{\delta, i})$  is constantly  $\gamma < \theta$  then we let

$$p_i = \left( \cup \{h^{q_\zeta^j} : j < i \text{ and } \zeta < \delta_i\} \cup \gamma_{[N_{\delta_i}^i \cap \kappa, \beta_i]}, \right. \\ \left. \text{closure}(\cup \{C^{q_\zeta^j} : j < i \text{ and } \zeta < \delta_i\} \cup \{\beta_i\}) \right)$$

for some  $\beta_i \in M_{i+1} \cap \kappa \setminus M_i$  large enough such that  $A_\delta \cap M_{i+1} \cap \kappa \subseteq \beta_i$ . □?  
 $\rightarrow$  `scite{2.10} undefined`

*Remark.* In the example of uniformizing (see [Sh 587]) if we use this forcing, the density is less problematic.

**2.14 Claim.** 1) In ?'s conclusion we can omit the club  $E$  that is let  $E = \kappa$  and  
 $\rightarrow$  `scite{2.10} undefined`  
demand  $(\forall \delta \in S)(h_\delta \subseteq^* h)$  provided that we add in ?, recalling  $S \subseteq \kappa$  does not  
 $\rightarrow$  `scite{2.10} undefined`  
reflect is a set of limit ordinals and

$$\bar{A} = \langle A_\delta : \delta \in S \rangle, A_\delta \subseteq \delta = \sup(A_\delta)$$

satisfies

$$(*) \delta_1 \neq \delta_2 \text{ in } S \Rightarrow \sup(A_{\delta_1} \cap A_{\delta_2}) < \delta_1 \cap \delta_2.$$

2) If  $(\forall \delta \in S)(otp(A_\delta) = \theta)$  this always holds.

*Proof.* We define  $\mathbb{Q} = \{h : \text{Dom}(h) \text{ is an ordinal } < \kappa \text{ and } h(\beta) \neq 0 \wedge \beta \in \text{Dom}(h) \rightarrow (\exists \delta \in S)[h_\delta(\beta) = h(\beta)] \text{ and } \delta \in (\text{Dom}(h) + 1) \cap S \text{ implies } h_\delta \subseteq^* h\}$  ordered by  $\subseteq$ . Now we should prove the parallel of the fact:

$\boxtimes'$  if  $p \in \mathbb{Q}, \alpha = \text{Dom}(p) < \beta < \kappa$  then there is  $q$  such that  $p \leq q \in \mathbb{Q}$  and  $\text{Dom}(q) = \beta$ .

Why this holds? We can find  $\langle A'_\delta : \delta \in S \cap (\beta + 1) \rangle$  such that  $A'_\delta \subseteq A_\delta, \sup(A_\delta \setminus A'_\delta) < \delta$  and  $\bar{A}' = \langle A'_\delta : \delta \in S \cap (\beta + 1) \rangle$  is pairwise disjoint.

Now choose  $q$  as follows

$$\text{Dom}(q) = \beta$$

$$q(j) = \begin{cases} p(j) & \text{if } j < \alpha \\ h_\delta(j) & \text{if } j \in A'_\delta \setminus \alpha \text{ and } \delta \in S \cap (\beta + 1) \setminus (\alpha + 1) \\ 0 & \text{if otherwise.} \end{cases}$$

Why does  $\bar{A}'$  exist? Prove by induction on  $\beta$  that for any  $\bar{A}^1, \langle A'_\delta : \delta \in S \cap (\alpha + 1) \rangle$  as above and  $\beta$  satisfying  $\alpha < \beta < \kappa$ , we can extend  $\bar{A}^1$  to  $\langle A'_\delta : \delta \in S \cap (\beta + 1) \rangle$  which is as above.  $\square_{2.14}$

*2.15 Remark.* Note: concerning  $\kappa$  inaccessible we could immitate what is here:

$$\text{having } M_{i+1} \not\prec_{\neq} N_{\delta_i}^i, \bigcup_{i < \delta} M_i = \bigcup_{i < \delta} N_{\delta_i}^i.$$

As long as we are looking for a proof that no sequence of length  $< \kappa$  are added, the gain is meagre (restricting the  $\bar{q}$ 's by  $\bar{q} \upharpoonright \alpha \in N'_{\alpha+1}$ ). Still if you want to make the uniformization and some diamond we may consider this.

2.16 Comment: We can weaken further the demand, by letting COM have more influence. E.g. we have (in 2.3)  $\delta_i = \lambda_i = \text{cf}(\lambda_i) = \|M_{i+1}\|, D_i$  a  $|a_i|^+$ -complete filter on  $\lambda_i$ , the choice of  $\bar{q}^i$  in the result of a game in which INC should have chose a set of player  $\in D_i$  and  $\diamond_{D_i}$  holds (as in the treatment of case  $E^*$  here).

The changes are obvious, but I do not see an application at the moment.

§3  $\kappa^+$ -C.C. AND  $\kappa^+$ -PIC

We intend to generalize pic of [Sh:f, Ch.VIII,§1]. The intended use is for iteration with each forcing  $> \kappa$  - see use in [Sh:f]. In [Sh 587, B.7.4] we assume each  $\mathbb{Q}_i$  of cardinality  $\leq \kappa$ . Usually  $\mu = \kappa^+$ .

Note:  $\hat{\mathcal{E}}_0$  is as in the accessible case, in [Sh 587] but this part works in the other cases. In particular, in Cases A,B (in [Sh 587]'s context) if the length of  $\bar{a} \in \hat{\mathcal{E}}_0$  is  $< \lambda$  (remember  $\kappa = \lambda^+$ ), then we have  $(< \lambda)$ -completeness implies  $\hat{\mathcal{E}}_0$ -completeness AND in 3.7 even  $\bar{a} \in \hat{\mathcal{E}}_0 \Rightarrow \ell g(\bar{a}) = \omega$  is O.K.

In Case A on the  $S_0 \subseteq S_\lambda^\kappa$  if  $\ell g(\bar{a}) = \lambda, a_\lambda \in S_0$  is O.K., too. STILL can start with other variants of completeness which is preserved.

**3.1 Context:** We continue [Sh 587, B.5.1-B.5.7(1)] (except the remark [Sh 587, B.5.2(3)]) under the weaker assumption  $\kappa = \kappa^{<\kappa} > \aleph_0$ , so  $\kappa$  is not necessarily strongly inaccessible; also in our  $\hat{\mathcal{E}}$ 's we allow  $\bar{a}$  such that  $|a_\delta| = |\delta|$  is strongly inaccessible.

**3.2 Definition.** Assume:

- ⊠(a)  $\mu = \text{cf}(\mu) > |\alpha|^{<\kappa}$  for  $\alpha < \mu$
- (b) the triple  $(\kappa, \mu^*, \hat{\mathcal{E}}_0)$  satisfies:  $\kappa = \text{cf}(\kappa) > \aleph_0, \mu^* \geq \kappa, \hat{\mathcal{E}}_0 \subseteq \{\bar{a} : \bar{a} \text{ an increasing continuous sequence of members of } [\mu^*]^{<\kappa} \text{ of limit length } < \kappa \text{ with } a_i \cap \kappa \in \kappa\}$  and
- (c)  $S^\square \subseteq \{\delta < \mu : \text{cf}(\delta) \geq \kappa\}$  stationary.

For  $\ell = 1, 2$  we say  $\mathbb{Q}$  satisfies  $(\mu, S^\square, \hat{\mathcal{E}}_0)$ -pic $_\ell$  if: for some  $x \in \mathcal{H}(\chi)$  (can be omitted, essentially, i.e. replaced by  $\mathbb{Q}$ ) we have

- (\*) if
  - ( $\alpha$ )  $S \subseteq S^\square$  is stationary and  $\langle \mu, S, \hat{\mathcal{E}}_0, x \rangle \in N_0^\alpha$
  - ( $\beta$ ) for  $\alpha \in S, \delta_\alpha < \kappa$ , and
    - (i) if  $\ell = 1, \bar{N}^\alpha = \langle N_i^\alpha : i \leq \delta_\alpha \rangle$  and  $c_\alpha = \delta_\alpha$  and  $\bar{N}^{\alpha,*} = \bar{N}^\alpha$
    - (ii) if  $\ell = 2$  then  $\bar{N}^{\alpha,*} = \langle N_i^\alpha : i \leq \delta_\alpha \rangle, \bar{N}^\alpha = \langle N_i^\alpha : i \in c_\alpha^+ \rangle$   
 where  $c_\alpha \subseteq \delta_\alpha = \sup(c_\alpha), c_\alpha^+ = c_\alpha \cup \{\delta_\alpha\}, c_\alpha$  is closed,  
 $\gamma < \beta \in c_\alpha \Rightarrow c_\alpha \cap \gamma \in N_\beta^\alpha$
  - ( $\gamma$ )  $(\bar{N}^\alpha, \bar{a}^\alpha)$  is  $\hat{\mathcal{E}}_0$ -complementary (see [Sh 587, B.5.3]); so  $\bar{N}^\alpha$  obeys  $\bar{a}^\alpha \in \hat{\mathcal{E}}_0$  (with some error  $n_\alpha$ ) (so here we have  $\|N_{\delta_\alpha}^\alpha\| < \kappa, \delta_\alpha < \kappa$ )
  - ( $\delta$ )  $\bar{p}^\alpha$  is  $(\bar{N}^\alpha, \mathbb{Q})^1$ -generic (see [Sh 587, Definition B.5.3.1])

- ( $\varepsilon$ )  $\alpha \in N_0^\alpha$  and
- (i) if  $\ell = 1$ , then for some club  $C$  of  $\mu$  for every  $\alpha \in S$  we have  $\langle (\bar{N}^\beta, \bar{p}^\beta) : \beta \in S \cap C \cap \alpha \rangle$  belong to  $N_0^\alpha$
  - (ii) if  $\ell = 2$ , then for some club  $C$  of  $\mu$  for every  $\alpha \in S \cap C$  and  $i < \delta_\alpha$  we have  $\langle (\bar{N}^{\beta,*} \upharpoonright (i+1), \bar{p}^\beta \upharpoonright (i+1)) : \beta \in S \cap C \rangle$  belongs to  $N_{i+1}^\alpha$
- ( $\varepsilon$ ) we define a function  $g$  with domain  $S$  as follows:  $g(\alpha) = (g_0(\alpha), g_1(\alpha))$  where  $g_0(\alpha) = N_{\delta_\alpha}^\alpha \cap (\bigcup_{\beta < \alpha} N_{\delta_\beta}^\beta)$  and  $g_1(\alpha) = (N_{\delta_\alpha}^\alpha, N_i^\alpha, c)_{i < \delta_1, c \in g_0(\alpha)} / \cong$ ,

then we can find a club  $C$  of  $\mu$  such that:  
 if  $\alpha < \beta$  &  $g(\alpha) = g(\beta)$  &  $\alpha \in C \cap S$  &  $\beta \in C \cap S$  then  $\delta_\alpha = \delta_\beta, g(\alpha) = g(\beta)$ , for some  $h, N_{\delta_\alpha}^\alpha \cong_h N_{\delta_\beta}^\beta$  (really unique), and for each  $i < \delta_\alpha$  the function  $h$  maps  $N_i^\alpha$  to  $N_i^\beta, p_i^\alpha$  to  $p_i^\beta$  and  $\{p_i^\alpha : i < \delta_\alpha\} \cup \{p_i^\beta : i < \delta_\beta\}$  has an upper bound.

**3.3 Claim.** Assume  $\boxtimes$ , i.e. (a), (b), (c) of 3.2 and

- (d)  $\hat{\mathcal{E}}_0$  is non-trivial, which means:  
 for every  $\chi$  large enough and  $x \in \mathcal{H}(\chi)$  there is  $\bar{N} = \langle N_i : i \leq \delta \rangle$  increasingly continuous,  $N_i \prec (\mathcal{H}(\chi), \in), x \in N_i, \|N_i\| < \kappa, \bar{N} \upharpoonright (i+1) \in N_{i+1}$  and  $\bar{N}$  obeys some  $\bar{a} \in \hat{\mathcal{E}}_0$  with some finite error  $n$ )
- (e)  $\mathbb{Q}$  is a strongly  $cl(\hat{\mathcal{E}}_0)$ -complete forcing notion (hence adding no new bounded subsets of  $\kappa$ ) where  $cl(\hat{\mathcal{E}}_0) =: \{\bar{a} \upharpoonright [\alpha, \beta] : \bar{a} \in \hat{\mathcal{E}}_0 \text{ and } \alpha \leq \beta \leq lg(\bar{a})\}$
- (f)  $\mathbb{Q}$  satisfies  $(\mu, S^\square, \hat{\mathcal{E}}_0)$ -pic $_\ell$  where  $\ell \in \{1, 2\}$ .

Then  $\mathbb{Q}$  satisfies the  $\mu$ -c.c. provided that

- (\*)  $\ell = 1$  or  $\ell = 2$  and  $\hat{\mathcal{E}}_0$  is fat, see below.

**3.4 Definition.** We say  $\hat{\mathcal{E}}_0 \in \mathfrak{C}_{<\kappa}^-(\mu^*)$  is fat, if in the following game  $\mathfrak{D}_{\kappa, \mu^*}(\hat{\mathcal{E}}_0)$  between fat and lean, the fat player has a winning strategy.

A play last  $\kappa$  moves; in the  $\alpha$ -th move:

Case 1:  $\alpha$  nonlimit.

The player lean chooses a club  $Y_\alpha \subseteq [\mu^*]^{<\kappa}$ , the fat player chooses  $a_\alpha \in Y_\alpha$  and  $\mathcal{P}_\alpha \subseteq \{c : c \subseteq \alpha \text{ is closed}\}$  of cardinality  $< \kappa$ .

Case 2:  $\alpha$  limit.

We let  $Y_\alpha = [\mu_0]^{<\kappa}$  and  $a_\alpha = \cup\{a_\beta : \beta < \alpha\}$  and the player fat chooses  $\mathcal{P}_\alpha \subseteq \{C : C \subseteq \alpha \text{ is closed}\}$  of cardinality  $< \kappa$ .

In a play, fat wins iff for some limit ordinal  $\alpha$  and  $c \in \mathcal{P}_\alpha$  we have:

- (\*) (i)  $\beta \in c \Rightarrow c \cap \beta \in \mathcal{P}_\beta$
- (ii)  $\alpha = \sup(c)$
- (iii)  $\langle a_\beta : \beta \in c \cup \{\alpha\} \rangle \in \hat{\mathcal{E}}_0$ .

*3.5 Remark.* 0) With more care in the game Definition 3.10 we incorporate choosing the  $\bar{p}^\alpha$ 's. In 3.7(\*) $(\varepsilon)$ (ii) we can add  $\langle N_{i+1}^\beta : \beta \in \alpha \cap c \rangle$  belongs to  $N_{i+1}^\alpha$ .

1) In the Definition 3.4, without loss of generality  $c \in \mathcal{P}_\alpha$  &  $\beta \in c \Rightarrow c \cap \beta \in \mathcal{P}_\beta$ .  
 2) If  $\kappa$  is strongly inaccessible without loss of generality we have  $\mathcal{P}_\alpha = \mathcal{P}(\alpha)$ , so fat has a winning strategy.

3) In general being fat is a weak demand, e.g. if  $\hat{\mathcal{E}}_0 \supseteq \{\bar{a} : \bar{a} = \langle a_i : i \leq \omega \rangle, a_\omega = \bigcup_n a_n, a_i \in [\mu^*]^{<\kappa} \text{ is increasing.}$

*Proof of 3.9. Case 1:*  $\ell = 1$ .

Assume  $p_\alpha \in \mathbb{Q}$  for  $\alpha < \mu$  and let  $\chi$  be large enough and  $x$  as in Definition 3.2. We choose  $(\bar{N}^\alpha, \bar{p}^\alpha)$  by induction on  $\alpha < \mu$  as follows. If  $\langle (\bar{N}^\beta, \bar{p}^\beta) : \beta < \alpha \rangle$  is already defined, as  $\hat{\mathcal{E}}_0$  is non-trivial there is a pair  $(\bar{N}^\alpha, \bar{a}^\beta)$  which is  $\hat{\mathcal{E}}_0$ -complementary and  $\langle (\bar{N}^\beta, \bar{p}^\beta) : \beta < \alpha \rangle, \mathbb{Q}, \langle p_\beta : \beta < \mu \rangle, p_\alpha, \alpha, x$  belong to  $N_0^\alpha$  and let  $\bar{N}^\alpha = \langle N_i^\alpha : i \leq \delta_i \rangle$ . So  $p_\alpha \in N_0^\alpha$  and we can choose  $p_{\alpha,i} \in N_{i+1}^\alpha$  such that  $p_\alpha = p_{\alpha,0}$  and  $\langle p_{\alpha,i} : i < \delta_\alpha \rangle$  is  $(\bar{N}^\alpha, \mathbb{Q})^1$ -generic.

[Why? By the proof of [Sh 587, B.5.6.4].] Now by “ $\mathbb{Q}$  is  $(\mu, S^\square, \hat{\mathcal{E}}_0)$ -pic $_\ell$ ”, for some  $\alpha < \beta$  in  $S^\square$ ,  $\{p_i^\alpha : i < \delta_\alpha\} \cup \{p_i^\beta : i < \delta_\beta\}$  has a common upper bound hence in particular,  $p_\alpha, p_\beta$  are compatible.

Case 2:  $\ell = 2$ .

Assume  $p_\alpha \in \mathbb{Q}$  for  $\alpha < \mu$  and let  $\chi$  be large enough. Let **St** be a winning strategy for the player fat in the game  $\partial_{\kappa, \mu^*}(\hat{\mathcal{E}}_0)$ . Now we choose by induction on  $i < \kappa$ . The tuple  $(N_i^\alpha, \mathcal{P}_i^\alpha, Y_i^\alpha, \bar{p}_i^\alpha)$  where  $\bar{p}_i^\alpha = \langle p_{i,c}^\alpha : c \in \mathcal{P}_i^\alpha \rangle$  for  $\alpha < \mu$  such that:

- ⊠(a)  $M_i^\alpha \prec (\mathcal{H}(\chi), \in, <_\chi^*)$
- (b)  $M_i^\alpha$  increasing continuous in  $i$
- (c)  $\|M_i^\alpha\| < \kappa$  and  $\langle M_j^\alpha : j \leq i \rangle \in M_{i+1}^\alpha$  and  $M_i^\alpha \cap \kappa \in \kappa$  and  $p_\alpha \in M_i^\alpha$ ,
- (d)  $\langle Y_j^\alpha, M_j^\alpha \cap \mu^*, \mathcal{P}_j^\alpha : j \leq i \rangle$  is an initial segment of a play of  $\partial_{\kappa, \mu^*}(\hat{\mathcal{E}}_0)$  in which the player fat uses his winning strategy **St**

- (e)  $\langle (M_j^\beta, \mathcal{P}_j^\beta, Y_j^\beta, \bar{p}_j^\beta) : j \leq i, \beta \in S \rangle$  belongs to  $N_{i+1}^\alpha$  (hence  $\mathcal{P}_j^\alpha \subseteq M_{j+1}^\alpha$ , etc.)
- (f)  $p_{i,c}^\alpha \in \mathbb{Q} \cap N_{i+1}^\alpha$
- (g) if  $c \in \mathcal{P}_i^\alpha$  and  $\langle p_{j,c \cap j}^\alpha : j \in c \rangle$  has an upper bound then  $p_{i,c}^\alpha$  is such a bound
- (h)  $p_{i,c}^\alpha \in \cap \{ \mathcal{S} : \mathcal{S} \in M_i^\alpha \text{ is a dense open subset of } \mathbb{Q} \}$ .

Can we carry the induction?

For  $i$  limit let  $M_i^\alpha = \cup \{ M_j^\alpha : j < i \}$  and choose  $Y_i^\alpha, \mathcal{P}_i^\alpha$  by clause (d) i.e. by the rules of the game  $\mathfrak{D}_{\kappa, \mu^*}(\hat{\mathcal{E}}_0)$  and  $p_i^\alpha$  by clause (g) + (h) (possible as forcing by  $\mathbb{Q}$  adds no new sequences of length  $< \kappa$  of members of  $\mathbf{V}$ ). For  $i$  non-limit, let  $x_i = \langle (M_j^\beta, \mathcal{P}_j^\beta, Y_j^\beta, \bar{p}_j^\beta) : j \leq i, \beta \in S \rangle$  let  $Y_i^\alpha = \{ a : a \in [\mu^*]^{< \kappa} \text{ and } \alpha \in a \text{ and } a = \mu^* \cap \text{Sk}_{(\mathcal{H}(x), \in, <^*)}^{< \kappa}(\{x_i \times \mathbb{Q}, \mathbf{St}, \alpha\}) \}$  ( $\text{Sk}^{< \kappa}$  means  $a \in Y_i^\alpha \Rightarrow a \cap \kappa \in \kappa$ ) and let  $(a_i^\alpha, \mathcal{P}_i^\alpha)$  be the move which the strategy  $\mathbf{St}$  dictate to the player fat if the  $i$ -th move of lean is  $Y_i^\alpha$  (and the play so far is  $\langle (Y_j^\alpha, M_j^\alpha \cap \mu^*, \mathcal{P}_{\alpha, j}) : j < i \rangle$ ). Now we choose  $M_i^\alpha = \text{Sk}_{(\mathcal{H}(x), \in, <^*)}^{< \kappa}(\{x_i, \mathbb{Q}, \mathbf{St}, \alpha\})$  and  $\mathcal{P}_i^\alpha$  has already been chosen and  $\bar{p}_i^\alpha = \langle p_{i,c}^\alpha : c \in \mathcal{P}_i^\alpha \rangle$  as in the limit case.

Having carried the induction, for each  $\alpha \in S$  in the play  $\langle (Y_i^\alpha, M_i^\alpha \cap \mu^*, \mathcal{P}_i^\alpha) : i < \kappa \rangle$  the player fat wins the game having used the strategy  $\mathbf{St}$ , hence there are a limit ordinal  $i_\alpha < \kappa$  and closed  $c_\alpha \in \mathcal{P}_{i_\alpha}$  and  $i_\alpha = \sup(c_\alpha)$  and  $\langle M_j^\alpha : j \in c_\alpha \cup \{i_\alpha\} \rangle$  obeys some member  $\bar{a}_\alpha$  of  $\hat{\mathcal{E}}_0$ . As  $\mathbb{Q}$  is  $\text{cl}(\hat{\mathcal{E}}_0)$ -complete we can prove by induction on  $j \in c_\alpha \cup \{i_\alpha\}$  that  $\varepsilon < j$  &  $\varepsilon \in C_\alpha \Rightarrow \mathbb{Q} \models p_{\varepsilon, c_\alpha \cap \varepsilon}^\alpha \leq p_{j, c_\alpha \cap j}^\alpha$ .

Let  $\delta_\alpha = i_\alpha, N_i^\alpha = M_i^\alpha$  for  $i \leq \delta_\alpha$  and  $\bar{p}^\alpha = \langle p_i^\alpha : i \in c_\alpha \rangle$ . Now continue as in Case 1. □<sub>3.3</sub>

**3.6 Claim.** *If (\*) of Definition 3.2, we can allow  $\text{Dom}(g)$  to be a subset of  $\text{Scap}C, \langle A_i : i < \mu \rangle$  be an increasingly continuous sequence of sets,  $|A_i| < \mu, N_{\delta_\alpha}^\alpha \subseteq A_{\alpha+1}$  replacing the definition of  $g, g_0$  and by  $g_0(\alpha) = N_{\delta_\alpha}^\alpha \cap A_\alpha$  and  $g_1$  by  $g_1(\alpha) = (N_{\delta_\alpha}^\alpha, N_i^\alpha, c)_{i < \delta_\alpha, c \in g_0(c)} / \cong$  (and get equivalent definition).*

*Remark.* If  $\text{Dom}(g) \cap S^\square$  is not stationary, the definition says nothing.

*Proof.* Straight.

**3.7 Claim.** *Assume clauses  $\boxtimes$ , i.e. (a), (b), (c) of 3.2 and (d) of 3.3.*

*For  $(< \kappa)$ -support iteration  $\bar{\mathbb{Q}} = \langle \mathbb{P}_i, \bar{\mathbb{Q}}_i : i < \alpha \rangle$ , if we have  $\Vdash_{\mathbb{P}_i}$  “ $\bar{\mathbb{Q}}_i$  is  $(\mu, S^\square, \hat{\mathcal{E}}_0)$ -pic $_\ell$ ” for each  $i < \alpha$  and forcing with  $\text{Lim}(\bar{\mathbb{Q}})$  add no bounded subsets of  $\kappa$ , then  $\mathbb{P}_\gamma$  and  $\mathbb{P}_\gamma / \mathbb{P}_\beta$ , for  $\beta \leq \gamma \leq \text{lg}(\bar{\mathbb{Q}})$  are  $\hat{\mathcal{E}}_0$ -complete  $(\mu, S^\square, \hat{\mathcal{E}}_0)$ -pic $_\ell$ .*

*3.8 Remark.* We can omit the assumption “Lim( $\bar{\mathbb{Q}}$ ) add no bounded subsets of  $\kappa$ ” if we add the assumption  $cl(\hat{\mathcal{E}}_0) \in \mathfrak{C}_{<\kappa}(\mu^*)$ , see [Sh 587, Def.B.5.1(2)], because with the later assumption the former follows by [Sh 587, B.5.6].

*Proof.* Similar to [Sh:f, Ch.VIII]. We first concentrate on

Case 1:  $\ell = 1$ .

It is enough to prove for  $\mathbb{P}_\alpha$ .

We prove this by induction on  $\alpha$ . Let  $\Vdash_{\mathbb{P}_i}$  “ $\mathbb{Q}_i$  is  $(\mu, S^\square, \hat{\mathcal{E}}_0)$ -pic $_\ell$  as witnessed by  $\underline{x}_i$  and let  $\chi_i = \text{Min}\{\chi : \underline{x}_i \in \mathcal{H}(\chi)\}$ ”.

Let  $x = (\mu^*, \kappa, \mu, S^\square, \hat{\mathcal{E}}_0, \langle(\chi_i, \underline{x}_i) : i < lg(\bar{\mathbb{Q}})\rangle)$  and assume  $\chi$  is large enough such that  $x \in \mathcal{H}(\chi)$  and let  $\langle(\bar{N}^\alpha, \bar{p}^\alpha) : \alpha \in S\rangle$  be as in Definition 3.2, so  $S \subseteq S^\square$  is stationary and  $\bar{N}^\alpha = \langle N_i^\alpha : i \leq \delta_\alpha \rangle$ . We define a  $g$  by

$\boxtimes_1$   $g$  is a function with domain  $S$

$\boxtimes_2$   $g(\alpha) = \langle g_\ell(\alpha) : \ell < 2 \rangle$  where

$$g_0(\alpha) = (N_{\delta_\alpha}^\alpha) \cap \left( \bigcup_{\beta < \alpha} N_{\delta_\beta}^\beta \right)$$

$$g_1(\alpha) = \text{the isomorphic type of } (N_{\delta_\alpha}^\alpha, N_i^\alpha, p_i^\alpha, c)_{c \in g_0(\alpha)}.$$

Let  $C$  be a club of  $\mu$  such that  $\alpha \in S \cap C \Rightarrow \langle(\bar{N}^\beta, \bar{p}^\beta) : \beta < \alpha\rangle \in N_0^\alpha$ , (recall  $\ell = 1$ ).

Fix  $y$  such that  $S_y = \{\alpha \in S : g(\alpha) = y \text{ and } \alpha \in C\}$  is stationary.

Let  $w_\alpha = \bigcup_{i < \delta_\alpha} \text{Dom}(p_i^\alpha)$ ,  $w_y^* = w_\alpha \cap g_0(\alpha)$  for  $\alpha \in S_y$  (as  $\alpha \in S_y$ , clearly the set does not depend on the  $\alpha$ ). For each  $\zeta \in w_y^*$  we define a  $\mathbb{P}_\zeta$ -name,  $\underline{S}_{y,\zeta}$  as follows:

$$\underline{S}_{y,\zeta} = \{\alpha \in S_y : (\forall i < \delta_\alpha)(p_i^\alpha \upharpoonright \zeta \in G_{\mathbb{P}_\zeta})\}.$$

Now we try to apply Definition 3.2 in  $\mathbf{V}^{\mathbb{P}_\zeta}$  to

$\left\langle \left( \langle N_i^\alpha[G_{\mathbb{P}_\zeta}] : i \leq \delta_\alpha \rangle, \langle p_i^\alpha(\zeta)[G_{\mathbb{P}_\zeta}] : i < \delta_\alpha \rangle \right) : \alpha \in \underline{S}_{y,\zeta}[G_{\mathbb{P}_\zeta}] \right\rangle$ . Clearly, if  $\underline{S}_{y,\zeta}[G_{\mathbb{P}_\zeta}]$  is a stationary subset of  $\mu$ , we can apply it and  $g_{y,\zeta}$  be the  $\mathbb{P}_\zeta$ -name of a function with domain  $\underline{S}_{y,\zeta}$  defined like  $g$  in (\*) of Definition 3.2. Now  $g_{y,\zeta}$  is well defined, and actually can be computed if we use  $A_\beta = \cup\{N_{\delta_\alpha}^\alpha[G_{\mathbb{P}_\zeta}] : \alpha < \beta\}$ . So by an induction hypothesis on  $\alpha$  there is a suitable  $\mathbb{P}_\zeta$ -name  $\underline{C}_\zeta$  of a club of  $\mu$  such that in addition, if  $\underline{S}_{y,\zeta}[G_{\mathbb{P}_\zeta}]$  is not a stationary subset of  $\mu$ , let  $\underline{C}_\zeta[G_{\mathbb{P}_\zeta}]$  be a club of  $\mu$

disjoint to it. But as  $\mathbb{P}_\zeta$  satisfies the  $\mu$ -c.c. without loss of generality  $C_\zeta = C_\zeta$  so  $C' = C \cap \bigcap_{\zeta \in w_y^*} C_\zeta$  is a club of  $\mu$ . Now choose  $\alpha_1 < \alpha_2$  from  $S_y \cap C'$  and we choose by induction on  $\varepsilon \in w' = w_y^* \cup \{0, \ell g(\bar{Q})\}$  a condition  $q_\varepsilon \in \mathbb{P}_\varepsilon$  such that:

- <sub>3</sub>(i)  $\varepsilon_1 < \varepsilon \Rightarrow q_{\varepsilon_1} = q_\varepsilon \upharpoonright \varepsilon_1$
- (ii)  $q_\varepsilon$  is a bound to  $\{p_u^{\alpha_1} \upharpoonright \varepsilon : i < \delta_{\alpha_1}\} \cup \{p_i^{\alpha_2} \upharpoonright \varepsilon : i < \delta_{\alpha_2}\}$ .

For  $\varepsilon = 0$  let  $q_0 = \emptyset$ . We have nothing to do really if  $\varepsilon$  is with no immediate predecessor in  $w$ , we let  $q_\varepsilon$  be  $\cup\{q_{\varepsilon_1} : \varepsilon_1 < \varepsilon, \varepsilon_1 \in w'\}$ . So let  $\varepsilon = \varepsilon_1 + 1, \varepsilon_1 \in w'$ ; now if  $q_\varepsilon \in G \subseteq \mathbb{P}_{\varepsilon_1, 2}, G$  generic over  $V$ , then  $\alpha_1, \alpha_2 \in S_{y, \varepsilon_1}[G]$ , hence  $S_{y, \zeta}[G] \cap C_{\varepsilon_1}$  is non-empty, hence is stationary, and we use Definition 3.2.

Case 2:  $p = 2$ .

Similar proof. □<sub>3.7</sub>

**3.9 Claim.** Assume  $\mu = cf(\mu) > \kappa, (\forall \alpha < \mu)(|\alpha|^{<\kappa} < \mu), S \subseteq \{\delta < \mu : cf(\delta) \geq \kappa\}$  is stationary. If  $|\mathbb{Q}| \leq \kappa$  or just  $< \mu, \mathcal{E}_0 \in \mathfrak{C}_{<\kappa}^-(\mu^*),$  that is  $\subseteq \{\bar{a} : \bar{a} \text{ increasingly continuous of length } < \kappa, a_i \in [\mu^*]^{<\kappa} \text{ and } a_i \cap \kappa \in \kappa\}$  non-trivial, possibly just for one cofinality say  $\aleph_0,$  then  $\mathbb{Q}$  satisfies  $\kappa^+$ -pic<sub>ℓ</sub>.

*Proof.* Trivial, we get same sequence of condition or just see the proof of [Sh 587, B.7.4]. □<sub>3.9</sub>

3.10 Discussion: 1) What is the use of pic?

In the forcing axioms instead “ $|\mathbb{Q}| \leq \kappa$ ” we can write “ $\mathbb{Q}$  satisfies the  $(\mu, S^\square, \hat{\mathcal{E}}_0)$ -pic”. This strengthens the axioms.

In [Sh:f] in some cases the length of the forcing is bounded (there  $\omega_2$ ) but here no need (as in [Sh:f, Ch.VII,§1]).

This section applies to all cases in [Sh 587] and its branches.

2) Note that we can demand that the  $p_i^\alpha$  satisfies some additional requirements (in Definition 3.2) say  $p_{2i}^\alpha = F_{\mathbb{Q}}(\bar{N} \upharpoonright (2i + 1), \bar{p}^\alpha \upharpoonright (2i + 1))$ .

Let us see how this gives some improvement of the results of [Sh 576, B.8] on  $\mathfrak{C}_{<\kappa}^\spadesuit(\mu^*),$  see [Sh 587, B.5.7.3].

**3.11 Definition.** Assume

- ⊗  $\kappa > \aleph_0$  is strongly inaccessible and  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1) \in \mathfrak{C}_{<\kappa}^\spadesuit(\mu^*)$  and  $\theta_0, \theta_1$  are regular cardinals  $> \kappa, \theta_2$  a cardinal  $> \kappa$  (let  $\hat{\theta} = (\theta_0, \theta_1, \theta_2)$ , the usual case is  $\theta_0 = \kappa^+$ ) and  $\hat{\mathcal{E}} \subseteq \hat{\mathcal{E}}_1$  is nontrivial (see in Definition 3.3, clause (d)) and  $\ell \in \{1, 2\}$ .

Let  $Ax_{\theta_1, \theta_2}^{\kappa}(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1, \mathcal{E})$ , the forcing axiom for  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1, \mathcal{E})$ , and  $\bar{\theta} = (\theta_0, \theta_1, \theta_2)$  be the following statement:

⊠ if

- (i)  $\mathbb{Q}$  is a forcing notion of cardinality  $< \theta_1$
- (ii)  $\mathbb{Q}$  is complete for  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ , see Definition [Sh 587, B.5.9(3)]
- (iii)  $\mathbb{Q}$  satisfies  $(\theta_0, S^\square, \hat{\mathcal{E}})$ -pic $_\ell$
- (iv)  $\mathcal{I}_i$  is a dense subset of  $\mathbb{Q}$  for  $i < i^* < \theta_2$ ,  
then there is a directed  $H \subseteq \mathbb{Q}$  such that  $(\forall i < i^*)(H \cap \mathcal{I}_i \neq \emptyset)$ .

**3.12 Theorem.** *Assume  $\otimes$  of Definition 3.11 and  $\mu = \mu^{<\theta_1} = \mu^{<\theta_0} \geq \theta_0 + \theta_2$ .  
Then there is a forcing notion  $\mathbb{P}$  such that:*

- ( $\alpha$ )  $\mathbb{P}$  is complete for  $\hat{\mathcal{E}}_0$
- ( $\beta$ )  $\mathbb{P}$  has cardinality  $\mu$
- ( $\gamma$ )  $\mathbb{P}$  satisfies the  $\theta_0$ -c.c. and even the  $(\kappa, \theta_0, \hat{\mathcal{E}})$ -pic $_\ell$
- ( $\delta$ )  $\mathbb{P}$  is complete for  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ , hence  $\Vdash_{\mathbb{P}} “(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1) \in \mathfrak{C}_{<\kappa}^\spadesuit(\mu^*)”$  and more
- ( $\varepsilon$ )  $\Vdash_{\mathbb{P}} “Ax_{\bar{\theta}}^{\kappa}(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1, \mathcal{E})”$ .

*Proof.* Like the proof of [Sh 587, B.8.2], using 3.7 instead of [Sh 587, B.7.4].  $\square_{3.12}$

We may wonder how large can a stationary  $S \subseteq \kappa$  be?

**3.13 Claim.** 1) *Assume*

- $\otimes$ (a)  $\kappa$  is strongly inaccessible  $> \aleph_0$
- (b)  $S \subseteq \kappa$  is stationary
- (c) for letting  $\mu^* = \kappa$  and  $\hat{\mathcal{E}}_0 = \hat{\mathcal{E}}_0[S] = \{\bar{a} \in \mathfrak{C}_{<\kappa}(\mu^*) : \text{for every } i \leq \text{lg}(\bar{a}) \text{ we have } a_i \notin S\}$  we have  $\hat{\mathcal{E}}_0 \in \mathfrak{C}_{<\kappa}(\mu^*)$
- (d) we let  $\hat{\mathcal{E}}_1 = \hat{\mathcal{E}}_1[S] = \{\bar{a} \in \mathfrak{C}_{<\kappa}(\mu^*) : \text{for every nonlimit } i \leq \text{ellg}(\bar{a}) \text{ we have } a_i \notin S\}$ .

Then

- ( $\alpha$ )  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1) \in \mathfrak{C}_{<\kappa}^\spadesuit(\mu^*)$ , see [Sh 587, B.5.7(3)].

2) *The parallel of 2.11.*

We now deal with forcing the failure of diamond on the set of inaccessibles.

**3.14 Claim.** *Assume*

- (a)  $\kappa, S, \hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1$  are as in 3.13
- (b) if  $S_{bd} =: \{\theta < \kappa : \theta \text{ strongly inaccessible, } S \cap \theta \text{ is stationary in } \theta \text{ and } \diamond_{S \cap \theta}\}$  is not a stationary subset of  $\kappa$
- (c)  $\bar{A} = \langle A_\alpha : \alpha \in S \rangle, A_\alpha \subseteq \alpha$
- (d)  $\mathbb{Q} = \mathbb{Q}_{\bar{A}_1}$  is as in Definition 3.15 below
- (e)  $\hat{\mathcal{E}} \subseteq \hat{\mathcal{E}}_0$  is nontrivial.

Then

- ( $\alpha$ )  $\mathbb{Q}$  is complete for  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$
- ( $\beta$ )  $\mathbb{Q}$  satisfies the  $(\kappa, \kappa^+, \hat{\mathcal{E}})$ -pic $_\ell$
- ( $\gamma$ )  $\mathbb{Q}$  satisfies the  $\kappa^+$ -c.c.

**3.15 Definition.** For  $\kappa = \text{cf}(\kappa), S \subseteq \kappa = \text{sup}(S), \bar{A} = \langle A_\alpha : \alpha \in S \rangle$ , with  $A_\alpha \subseteq \alpha$  we define the forcing notions  $\mathbb{Q} = \mathbb{Q}_{\bar{A}}^{ad}$  as follows:

- (a)  $p \in \mathbb{Q}$  iff
  - (i)  $p = (c, A) = (c^p, A^p)$
  - (ii)  $c$  is  $\emptyset$  or a closed bounded subset of  $\kappa$  hence has a last element
  - (iii)  $A \subseteq \text{sup}(c)$  such that
  - (iv) if  $\alpha \in C \cap S$  then  $A \cap \alpha \neq A_\alpha$
- (b)  $p \leq q$  iff
  - (i)  $c^p$  is an initial segment of  $c^q$
  - (ii)  $A^p = A^q \cap \text{sup}(c^p)$ .

*Proof of 3.14.* We concentrate on part (1), part (2)'s proof is similar. Now

- (\*)<sub>1</sub> for every  $\alpha < \kappa, \mathcal{I}_\alpha = \{p \in \mathbb{Q} : \alpha < \text{sup}(c^p)\}$  is dense open.  
 [Why? If  $p \in \mathbb{Q}$ , let  $\beta = \text{sup}(c^p) + 1 + \alpha$  and  $q = (c^p \cup \{\beta\}, A^p)$ , so  $p \leq q \in \mathcal{I}_\alpha$ .]
- (\*)<sub>2</sub> If  $\delta < \kappa$  is a limit ordinal,  $\langle p_i : i < \delta \rangle$  is  $\leq_{\mathbb{Q}}$ -increasing and  $\text{sup}(c^{p_i}) \leq \alpha_{i+1} < \text{sup}(c^{p_{i+1}})$  for  $i < \delta$ , and for limit  $i, \alpha_i = \cup\{\alpha_j : j < i\}$  and  $\{\alpha_{1+i} : i < \delta\}$

is disjoint to  $S$ , then  $p = (\bigcup_{i < \delta} c_i^{p_i}, \bigcup_{i < \delta} A^{p_i})$  is a  $\leq_{\mathbb{Q}}$ -lub of  $\langle p_i : i < \delta \rangle$ .

[Why? Just think.]

(\*)<sub>3</sub> forcing with  $\mathbb{Q}$  add no new sequences of length  $< \kappa$  of ordinals (or members of  $\mathbf{V}$ ).

[Why? By (\*)<sub>2</sub>+ the assumption  $\otimes$ , clause (c) of Claim 3.13 as in [Sh 587, B.6].]

(\*)<sub>4</sub>  $\mathbb{Q}$  is complete for  $\hat{\mathcal{E}}_0$

[Why? Just think.]

(\*)<sub>5</sub>  $\mathbb{Q}$  is complete for  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ , see [Sh 587, Def.B.5.9(3)].

[Why? Let  $\chi$  be large enough and let  $\langle M_i : i < \delta \rangle$  be ruled by  $(\hat{\mathcal{E}}_0, \hat{\mathcal{E}}_1)$ , with  $\hat{\mathcal{E}}_0$ -approximation  $\langle (\bar{N}^i, \bar{a}^i) : i < \delta \rangle$ , see [Sh 587, Def.B.5.9(1)] and  $r \in \mathbb{Q} \cap M_0$  and  $S, \kappa, \bar{A} \in M_0$  and we have to prove that the player COM has a winning strategy in the game  $\mathfrak{D}_{\bar{M}, \langle \bar{N}^i : i < \delta \rangle}(\mathbb{Q}, r)$ .]

For this we proved by induction on  $\delta < \kappa$  (a limit ordinal) the statement

$\boxtimes_{\delta}$  if  $\langle M_i : i \leq \delta \rangle, \langle \bar{N}^i : i < \delta \rangle, r$  are as above (but  $\alpha$  may be a nonlimit ordinal)  $\bar{b} = \langle b_i : i < \delta \rangle, b_i \in [M_{i+1} \cap \kappa \setminus M_i]^{\leq \|M_i\|}$  and  $B \subseteq M_{\delta} \cap \kappa$  (or just  $B \subseteq \cup \{b_i : i < \delta\}$ ), then we can find  $p$  such that  $r \leq p \in \mathbb{Q}$  and  $A^p \cap b_i = B \cap b_i$  for every  $i < \delta$  and  $\sup(c^p) = M_{\delta} \cap \kappa$ .

Case 1:  $\alpha$  nonlimit. Trivial.

Case 2:  $\alpha$  limit and for some  $i < \alpha$  we have  $\text{cf}(\delta) \leq \|M_i\|$ .

Let  $\theta = \text{cf}(\theta)$  and let  $\langle \delta_{\varepsilon} : \varepsilon \leq \theta \rangle$  be increasing continuous,  $\delta_0 = 0, \|M_{\delta_1}\| > \theta$  and  $\delta_{\theta} = \delta$ .

Choose  $b \subseteq M_{\delta_1+1} \cap \kappa \setminus M_{\delta_1} \setminus b_{\delta_1}$  of cardinality  $\theta$  and choose  $b' \subseteq b$  such that  $\zeta \in (\varepsilon, \delta] \Rightarrow A_{M_{\delta_{\zeta}} \cap \kappa} \cap b \neq b'$ . By the induction hypothesis, we can find  $r_{\delta_1} \in M_{\delta_1+1}$  such that  $\sup(c^{r_1}) = M_{\delta_1} \cap \kappa, r \leq r_{\delta_0}, \beta < \delta_1 \Rightarrow A^{r_1} \cap b_{\beta} = B \cap b_{\beta}$  and  $r_1$  is  $(M_{\beta}, \mathbb{Q})$ -generic for every  $\beta \leq \delta_1$ . Let  $r_1^+$  be such that  $r_{\delta_1} \leq r_1^+ \in \mathbb{Q} \cap M_{\delta_1+1}$  and  $\sup(b_{\delta_1} \cup b) < \sup(r_1^+)$  and  $A^{r_1^+} \cap b_{\delta_1} = B \cap b_{\delta_1}$  and  $A^{r_1^+} \cap b = b'$ . Now we choose by induction on  $\varepsilon \in [2, \delta]$ , a condition  $r_{\varepsilon}$  such that  $r_{\varepsilon} \in M_{\delta_{\varepsilon}+1}, \sup(c^{r_{\varepsilon}}) = M_{\delta_{\varepsilon}} \cap \kappa, r_1^+ \leq r_{\varepsilon}, [\zeta \in [2, \varepsilon] \Rightarrow r_{\zeta} \leq r_{\varepsilon}]$  and  $\beta < \delta_{\varepsilon} \Rightarrow A^{r_{\varepsilon}} \cap b_{\beta} = B \cap b_{\beta}$  and  $r_{\varepsilon}$  is  $(M_{\gamma}, \mathbb{Q})$ -generic for  $\gamma \leq \delta_{\varepsilon}$ . For limit  $\varepsilon, r_{\varepsilon}$  is uniquely determined and it  $\in \mathbb{Q}$  by the choice of  $r_1^+$ . For  $\varepsilon$  nonlimit use the induction hypothesis for  $\langle M_{\beta} : \beta \in [\delta_{\varepsilon} + 1, \delta_{\varepsilon+1}] \rangle$ .

Case 3: Neither Case 1 nor Case 2.

So  $\alpha$  is strongly inaccessible, call it  $\theta$  and  $\theta = M_{\theta} \cap \kappa$ ; so as  $\{\kappa, S\} \in M_{\theta} \prec (\mathcal{H}(\chi), \in, <_{\chi}^*)$ , necessarily  $\delta = \sup(S), \delta \in S_{\text{bd}}$  and  $\neg \diamond_{\theta \cap S}$  (e.g.  $\theta \cap S$  is not

stationary in  $S$ ). Choose for each  $\beta < \theta$ , an ordinal  $\gamma_\beta \in M_{\beta+1} \cap \kappa \setminus M_\beta \setminus b_\beta$  and let  $A'_i = \{j < i : \gamma_j \in A_{M_\beta \cap \kappa}\}$  for  $i \in S \cap \theta$ .

Now  $\langle A'_i : i \in S \cap \theta \rangle$  cannot be a diamond sequence for  $\theta$  hence we can find  $X \subseteq \theta$  and club  $C^-$  of  $\theta$  such that  $\delta \in X \cap S \Rightarrow A'_\delta \neq X \cap \delta$ . Let  $C = \{i < \theta : i \text{ limit, } (\forall j < i)(\gamma_j < i) \text{ and } i \in C^- \text{ and } M_i \cap \kappa = i\}$ , clearly  $C$  is a club of  $\theta$ . Let  $b_\beta^+ = a_\beta \cup \{\gamma_\beta\}$ ,  $B^+ = B \cup \{\gamma_\beta : \beta \in X\}$ , and proceed naturally.  $\square_{3.14}$

*3.16 Remark.* So we can iterate and get that (G.C.H. and) diamond fail for “most” stationary subsets of any strongly inaccessible. We shall return to this elsewhere.

§4 EXISTENCE OF NON-FREE WHITEHEAD (AND  
EXT( $G, \mathbb{Z}$ ) =  $\{0\}$ ) ABELIAN GROUPS IN SUCCESSOR OF SINGULARS

In [Sh 587], the consistency with GCH of the following is proved for some regular uncountable  $\kappa$ : there is a  $\kappa$ -free nonfree abelian group of cardinality  $\kappa$ , and all such groups are Whitehead. We use  $\kappa$  inaccessible, here we ask: is this assumption necessary for the first such  $\kappa$ ?

The following claim seems to support the hope for a positive answer.

**4.1 Claim.** *Assume*

- (a)  $\lambda$  is strong limit singular,  $\sigma = \text{cf}(\lambda) < \lambda, \kappa = \lambda^+ = 2^\lambda$
- (b)  $S \subseteq \{\delta < \kappa : \text{cf}(\delta) = \sigma\}$  is stationary
- (c)  $S$  does not reflect or at least
- (c)<sup>-</sup>  $\bar{A} = \langle A_\delta : \delta \in S \rangle, \text{otp}(A_\delta) = \sigma, \text{sup}(A_\delta) = \delta$  and  
 $\bar{A}$  is  $\lambda$ -free, i.e., for every  $\alpha^* < \kappa$  we can find  $\langle \alpha_\delta : \delta \in \alpha^* \cap S \rangle, \alpha_\delta < \delta$  such that  $\langle A_\delta \setminus \alpha_\delta : \delta \in S \cap \alpha^* \rangle$  is a sequence of pairwise disjoint sets
- (d)  $\langle G_i : i \leq \sigma \rangle$  is a sequence of abelian groups such that:
  - ( $\alpha$ )  $\delta < \sigma$  limit  $\Rightarrow G_\delta = \bigcup_{i < \delta} G_i$
  - ( $\beta$ )  $i < j \leq \sigma \Rightarrow G_j/G_i$  free and  $G_i \subseteq G_j$
  - ( $\gamma$ )  $G_\sigma / \bigcup_{i < \sigma} G_i$  is not Whitehead
  - ( $\delta$ )  $|G_\sigma| < \lambda$
  - ( $\varepsilon$ )  $G_0 = \{0\}$ .

Then

- 1) There is a strongly  $\kappa$ -free abelian group of cardinality  $\kappa$  which is not Whitehead, in fact  $\Gamma(G) \subseteq S$ .
- 2) There is a strongly  $\kappa$ -free abelian group  $G^*$  of cardinality  $\kappa$  satisfying  $\text{HOM}(G^*, \mathbb{Z}) = \{0\}$ , in fact  $\Gamma(G^*) \subseteq S$  (in fact the same abelian group can serve).
- 3) We can rephrase clause (d)( $\gamma$ ) of the assumption, i.e. " $G_\sigma / \bigcup_{i < \sigma} G_i$  is not Whitehead" by:

(d)( $\gamma$ )<sup>-</sup> some  $f^* \in \text{HOM}(\bigcup_{i < \sigma} G_i, \mathbb{Z})$  cannot be extended to  $f' \in \text{HOM}(G_\sigma, \mathbb{Z})$ .

We first note:

**4.2 Claim.** *Assume*

- (a)  $\lambda$  strong limit singular,  $\sigma = \text{cf}(\lambda) < \lambda, \kappa = 2^\lambda = \lambda^+$
- (b)  $S \subseteq \{\delta < \kappa : \text{cf}(\delta) = \sigma \text{ and } \lambda^\omega \text{ divides } \delta \text{ for simplicity}\}$  is stationary
- (c)  $A_\delta \subseteq \delta = \sup(A_\delta)$ ,  $\text{otp}(A_\delta) = \sigma$ ,  $A_\delta = \{\alpha_{\delta,\zeta} : \zeta < \sigma\}$  increasing with  $\zeta$
- (d) let  $h_0 : \kappa \rightarrow \kappa$  and  $h_1 : \kappa \rightarrow \sigma$  be such that  
 $(\forall \alpha < \kappa)(\forall \zeta < \sigma)(\forall \gamma \in (\alpha, \kappa))(\exists^\lambda \beta \in [\gamma, \gamma + \lambda])(h_0(\beta) = \alpha \text{ and } h_1(\beta) = \zeta)$ ,  
and  $(\forall \alpha < \kappa)h_0(\alpha) \leq \alpha$
- (e) Let  $\bar{\lambda} = \langle \lambda_\zeta : \zeta < \sigma \rangle$  be increasing continuous with limit  $\lambda$  such that  $\lambda_0 = 0$   
and  $\zeta < \sigma \Rightarrow \lambda_{\zeta+1} = \text{cf}(\lambda_{\zeta+1}) > \sigma$ .

Then we can choose  $\langle (g_\delta, \langle \gamma_\zeta^\delta : \zeta < \lambda \rangle) : \delta \in S \rangle$  such that

- $\odot_1$ (i)  $\langle \gamma_\zeta^\delta : \zeta < \lambda \rangle$  is strictly increasing with limit  $\delta$
- (ii) if  $\lambda_\zeta \leq \xi < \lambda_{\zeta+1}$  then  $h_0(\gamma_\xi^\delta) = h_0(\gamma_{\lambda_\zeta}^\delta) = \alpha_{\delta,\zeta}$  and  $h_1(\gamma_\xi^\delta) = h_1(\gamma_{\lambda_\zeta}^\delta) = \zeta$
- (iii)  $h_\delta^*$  a partial function from  $\kappa$  to  $\kappa$ ,  $\text{sup}(\text{Dom}(h_\delta^*)) < \gamma_\zeta^\delta$  for  $\delta \in S$
- $\odot_2$  for every  $f : \kappa \rightarrow \kappa, B \in [\kappa]^{<\lambda}$  and  $g_\zeta^2 : \kappa \rightarrow \lambda_{\zeta+1}$  for  $\zeta < \sigma$  there are  
stationarily many  $\delta \in S$  such that:
  - (i)  $h_\delta^* = f \upharpoonright B$
  - (ii) if  $\lambda_\zeta \leq \xi < \lambda_{\xi+1}$  then  $g_\zeta^2(\gamma_\xi^\delta) = g_\zeta^2(\gamma_{\lambda_\zeta}^\delta)$ .

*Remark.* Note that when subtraction or division<sup>3</sup> is meaningful,  $\odot_2$  is quite strong.

*Proof.* By the proofs of 1.1, 1.2 (can use guessing clubs by  $\alpha_{\delta,\zeta}$ 's, can demand that  $\beta_{2\zeta}^\delta, \beta_{2\zeta+1}^\delta \in [\alpha_{\delta,\zeta}, \alpha_{\delta,\zeta} + \lambda)$ .

But to help the reader we give a proof.

Let  $\lambda = \sum_{i < \sigma} \lambda_i, \lambda_i$  increasing continuous,  $\lambda_{i+1} > 2^{\lambda_i}, \lambda_0 = 0, \lambda_1 > 2^\sigma$ . Let  $M_i \prec (\mathcal{H}((2^\kappa)^+), \in, <^*)$  be increasing continuous,  $\|M_i\| = \lambda, \langle M_j : j \leq i \rangle \in M_{i+1}, \lambda + 1 \subseteq M_i$  and  $\{\bar{A}, h_0, h_1, \bar{\lambda}\} \in M_0$ . For  $\alpha < \lambda^+$ , let  $\alpha = \bigcup_{i < \sigma} a_{\alpha,i}$  such that  $|a_{\alpha,i}| \leq \lambda_i$  and  $a_{\alpha,i} \in M_{\alpha+1}$  and even  $\langle \langle a_{\beta,i} : i < \sigma \rangle : \beta \leq \alpha \rangle \in M_{\alpha+1}$ . Without loss of generality  $\delta \in S \Rightarrow \delta$  divisible by  $\lambda^\omega$  (ordinal exponentiation). For  $\delta \in S$

<sup>3</sup>i.e.  $x_\beta$  belongs to some additive group  $G^*$  for  $\beta < \kappa, \hat{g} \in \text{Hom}(G^*, H^*), g(\beta) = \hat{g}(x_\beta)$  then for some  $\delta$  as in  $\odot_2$ , we have  $g(x_{\beta_\xi}^\delta - x_{\beta_{\lambda_\zeta}}^\delta)$  is  $0_{H^*}$ ; similarly for multiplicative groups

let  $\bar{\beta}^\delta = \langle \beta_i^\delta : i < \sigma \rangle$  be increasing continuous with limit  $\delta, \beta_i^\delta$  divisible by  $\lambda$  and  $> 0$ . For  $\delta \in S$  let  $\langle b_i^\delta : i < \sigma \rangle$  be such that:  $b_i^\delta \subseteq \beta_i^\delta, |b_i^\delta| \leq \lambda_i, b_i^\delta$  is increasingly continuous in  $i$  and  $\delta = \bigcup_{i < \sigma} b_i^\delta$  (e.g.  $b_i^\delta = \bigcup_{j_1, j_2 < i} a_{\beta_{j_1, j_2}^\delta} \cup \lambda_i$ ). We

further demand  $\lambda_i \subseteq b_i^\delta \cap \lambda$ . Let  $\langle f_\alpha^* : \alpha < \lambda^+ \rangle$  list the two-place functions with domain an ordinal  $< \lambda^+$  and range  $\subseteq \lambda^+$ . Let  $H$  be the set of functions  $h, \text{Dom}(h) \in [\kappa]^{< \lambda}, \text{Rang}(h) \subseteq \kappa$ , so  $|H| = \kappa$ . Let  $S = \cup \{S_h : h \in H\}$ , with each  $S_h$  stationary and  $\langle S_h : h \in H \rangle$  pairwise disjoint. Without loss of generality  $\delta \in S_h \Rightarrow \sup(\text{Dom}(h)) < \beta_0^\delta$ . Let  $h_\delta^*$  be  $h$  when  $\delta \in S_h$ . We now fixed  $h \in H$  and will choose  $\bar{\gamma}^\delta = \langle \gamma_i^\delta : i < \lambda \rangle$  for  $\delta \in S_h$  such that clauses  $\odot_1 + \odot_2$  for our fixed  $h$  (and  $\delta \in S_h$  ignoring  $h$  in  $\odot_2$ ) hold, this clearly suffices.

Now for  $\delta \in S_h$  and  $i < \sigma$  and  $g \in {}^\sigma \sigma$  we can choose  $\zeta_{i, g, \varepsilon}^\delta$  (for  $\varepsilon < \lambda_{i+1}$ ) such that:

- (A)  $\langle \zeta_{i, g, \varepsilon}^\delta : \varepsilon < \lambda_{i+1} \rangle$  is a strictly increasing sequence of ordinals
- (B)  $\beta_i^\delta < \zeta_{i, g, \varepsilon}^\delta < \beta_{i+1}^\delta$ , (can even demand  $\zeta_{i, j, \varepsilon}^\delta < \beta_i^\delta + \lambda$ )
- (C)  $h_0(\zeta_{i, g, \varepsilon}^\delta) = \alpha_{\delta, i}$  and  $h_1(\zeta_{i, g, \varepsilon}^\delta) = i$
- (D) for<sup>4</sup> every  $\alpha_1, \alpha_2 \in b_{g(i)}^\delta$ , the sequence  $\langle \text{Min}\{\lambda_{g(i)}, f_{\alpha_1}^*(\alpha_2, \zeta_{i, g, \varepsilon}^\delta) : \varepsilon < \lambda_{i+1}\} \rangle$  is constant i.e. one of the following occurs:
  - ( $\alpha$ )  $\varepsilon < \lambda_{i+1} \Rightarrow (\alpha_2, \zeta_{i, g, \varepsilon}^\delta) \notin \text{Dom}(f_{\alpha_1}^*)$
  - ( $\beta$ )  $\varepsilon < \lambda_{i+1} \Rightarrow f_{\alpha_1}^*(\alpha_2, \zeta_{i, g, \varepsilon}^\delta) = f_{\alpha_1}^*(\alpha_2, \zeta_{i, j, 0}^\delta)$  well defined
  - ( $\gamma$ )  $\varepsilon < \lambda_j, f_{\alpha_1}^*(\alpha_2, \zeta_{i, g, \varepsilon}^\delta) \geq \lambda_j$ , well defined. We can add  $\langle f_{\alpha_1}^*(\alpha_2, \zeta_{i, g, \varepsilon}^\delta) : \varepsilon < \lambda_i \rangle$  is constant or strictly increasing.

- (E) for some  $j < \sigma$ , we have  $(\forall \varepsilon < \lambda_{i+1})[\zeta_{i, g, \varepsilon}^\delta \in a_{\alpha, j}]$  where  $\alpha = \sup\{\zeta_{i, g, \varepsilon}^\delta : \varepsilon < \lambda_{i+1}\}$ , (remember  $\sigma \neq \lambda_{i+1}$  are regular).

For each function  $g \in {}^\sigma \sigma$  we try  $\bar{\gamma}^{g, \delta} = \langle \gamma_\varepsilon^{\delta, g} : \varepsilon < \lambda \rangle$  be: if  $\lambda_i \leq \varepsilon < \lambda_{i+1}$  then  $\gamma_\alpha^{\delta, g} = \zeta_{i, g, \varepsilon}^\delta$ .

Now for some  $g$  it works. □<sub>4.2</sub>

*Proof of 1.2(1).* Let  $M = \cup \{M_\alpha : \alpha < \kappa\}, M_\alpha \prec (\mathcal{H}(2^\kappa)^+, \in)$  has cardinality  $\lambda, M_\alpha$  is increasing continuous,  $\langle M_\beta : \beta \leq \alpha \rangle \in M_\alpha$  and  $\langle F_i : i < \sigma \rangle$  belongs to  $M_0$ . Let  $E_0 = \{\delta < \kappa : M_\delta \cap \kappa = \delta\}$  and  $E = \text{acc}(E)$ . The proof is like the proof of 4.2 with the following changes:

- (i)  $\beta_i^\delta \in E_0$  for  $\delta \in S \cap E$

---

<sup>4</sup>we can use a colouring which uses e.g.  $\langle \zeta_{j, g, \varepsilon}^\delta : j < i, \varepsilon < \lambda_{j+1} \rangle$  as a parameter

(ii) in clause (A) we demand  $\langle \zeta_{i,g,\varepsilon}^\delta : g \in G, \varepsilon < \lambda_{i+1} \rangle$  belongs to  $M_{\beta_{i+1}^\delta}$  (hence also  $\langle \zeta_{j,g,\varepsilon}^\delta : g \in G, \varepsilon < \lambda_{j+1} : j \leq i \rangle$  belongs to  $M_{\beta_{i+1}^\delta}$ )

(iii) clause (c) is replaced by:  $\zeta_{i,g,\varepsilon}^\delta \in F_i(\{\zeta_{j,g|(j+1),\varepsilon}^\delta : \varepsilon < \lambda_{j+1} \text{ and } j < i\})$ .

□<sub>1.2</sub>

*Proof of 4.1.* 1) We apply 4.2 to the  $\langle A_\delta : \delta \in S \rangle$  from 4.1, and any  $h_0, h_1$  as in clause (d) of 4.2.

Let  $\{t_\gamma^{i,j} + G_i : \gamma < \theta^{i,j}\}$  be a free basis of  $G^j/G^i$  for  $i < j \leq \sigma$ . If  $i = 0, j = \sigma$  we may omit the  $i, j$ , i.e.  $t_\zeta = t_\zeta^{0,\sigma}$  and  $\theta = \theta^{0,\sigma}$ . Let  $\theta + \aleph_0 = |G_\sigma| < \lambda$ ; actually  $\theta^{\zeta,\zeta+1} < \lambda_\zeta$  is enough; without loss of generality  $\theta < \lambda_1$  in 4.2. Let  $\beta_{\zeta,i}^\delta = \gamma_{\xi(\zeta,i)}^\delta$  where  $\xi(\zeta, i) = \bigcup_{\varepsilon < \zeta} \lambda_\varepsilon + 1 + i$  for  $\delta \in S, \zeta < \sigma, i < \theta$ .

Let  $\beta_\delta(*) = \text{Min}\{\beta : \beta \in \text{Dom}(h_\delta^*), h_\delta^*(\beta) \neq 0\}$ , if well defined where  $h_\delta^*$  is from 4.2.

Clearly (see  $\odot_1$ (iii) of 4.2) we have  $\beta_\delta(*) \notin \{\beta_{\zeta,i}^\delta : \zeta < \sigma, i < \theta\}$  (or omit  $\lambda_\zeta, \beta_{\zeta,i}^\delta$  for  $\zeta$  too small). We define an abelian group  $G^*$ : it is generated by  $\{x_\alpha : \alpha < \kappa\} \cup \{y_\gamma^\delta : \gamma < \theta \text{ and } \delta \in S\}$  freely except for the relations:

$$(*)_1 \sum_{\gamma < \theta} a_\gamma y_\gamma^\delta = \sum \{b_{\zeta,\gamma} (x_{\beta_{\zeta,\gamma}^\delta} - x_{\gamma_{\lambda_\zeta}^\delta}) : \zeta < \sigma \text{ and } \gamma < \theta^{\zeta,\zeta+1}\}$$

when  $G_\sigma \models \sum_{\gamma < \theta^{0,\sigma}} a_\gamma t_\gamma = \sum \{b_{\zeta,\gamma} t_\gamma^{\zeta,\zeta+1} : \zeta < \sigma \text{ and } \gamma < \theta^{\zeta,\zeta+1}\}$  where  $a_\gamma, b_{\zeta,\gamma} \in \mathbb{Z}$  but all except finitely many are zero.

There is a (unique) homomorphism  $\mathbf{g}_\delta$  from  $G_\sigma$  into  $G^*$  induced by  $\mathbf{g}_\delta(t_\gamma) = y_\gamma^\delta$ . As usual it is an embedding. Let  $\text{Rang}(\mathbf{g}_\delta) = G^{<\delta>}$ .

For  $\beta < \kappa$  let  $G_\beta^*$  be the subgroup of  $G^*$  generated by  $\{x_\alpha : \alpha < \beta\} \cup \{y_\gamma^\delta : \gamma < \theta^{0,\sigma} \text{ and } \delta \in \beta \cap S\}$ . It can be described similarly to  $G^*$ .

**Fact A:**  $G^*$  is strongly  $\lambda$ -free.

*Proof.* For  $\alpha^* < \beta^* < \kappa$ , we can find  $\langle \alpha_\delta : \delta \in S \cap (\alpha^*, \beta^*] \rangle$  such that  $\langle A_\delta \setminus \alpha_\delta : \delta \in S \cap (\alpha^*, \beta^*] \rangle$  are pairwise disjoint and disjoint to  $\alpha^*$  hence the sequence  $\langle \{\beta_{\zeta,i}^\delta : i < \theta, \zeta \in (\text{Min}\{\xi < \sigma : \beta_{\zeta,0}^\delta > \alpha_\delta\}, \sigma)\} : \delta \in S \cap (\alpha^*, \beta^*] \rangle$  is a sequence of pairwise disjoint sets.

For  $\delta \in S \cap (\alpha^*, \beta^*]$ , let  $\zeta_\delta = \text{Min}\{\zeta : \beta_{\zeta,0}^\delta > \alpha_\delta\} < \sigma$ . Now easily  $G_{\beta^*+1}^*$  is generated as an extension of  $G_{\alpha^*+1}^*$  by  $\{\mathbf{g}_\delta(t_\gamma^{\zeta_\delta,\sigma}) : \gamma < \theta^{\zeta_\delta,\sigma} \text{ and } \delta \in S \cap (\alpha^*, \beta^*]\} \cup \{x_\alpha :$

$\alpha \in (\alpha^*, \beta^*]$  and for no  $\delta \in S \cap (\alpha^*, \beta^*]$  do we have  $\alpha \in \{\beta_{\zeta, i}^\delta : i < \theta^{\zeta, \sigma} \text{ and } \zeta < \zeta_\delta\}$ ; moreover  $G_{\beta^*+1}^*$  is freely generated (as an extension of  $G_{\alpha^*+1}^*$ ). So  $G_{\beta^*+1}^*/G_{\alpha^*+1}^*$  is free, as also  $G_1^*$  is free we have shown Fact A.

Fact B:  $G^*$  is not Whitehead.

*Proof.* We choose by induction on  $\alpha \leq \kappa$ , an abelian group  $H_\alpha$  and a homomorphism  $\mathbf{h}_\alpha : H_\alpha \rightarrow G_\alpha^* = \langle \{x_\beta : \beta < \alpha\} \cup \{y_\gamma^\delta : \gamma < \theta, \delta \in S \cap \alpha\} \rangle_{G^*}$  increasing continuous in  $\alpha$ , with kernel  $\mathbb{Z}$ ,  $\mathbf{h}_0 = \text{zero}$  and  $\mathbf{k}_\alpha : G_\alpha^* \rightarrow H_\alpha$  is a not necessarily linear mapping such that  $\mathbf{h}_\alpha \circ \mathbf{k}_\alpha = \text{id}_{G_\alpha^*}$ . We identify the set of members of  $H_\alpha, G_\alpha, \mathbb{Z}$  with subsets of  $\lambda \times (1 + \alpha)$  such that  $O_{H_\alpha} = O_{\mathbb{Z}} = 0$ .

Usually we have no freedom or no interesting freedom. But we have for  $\alpha = \delta + 1$ ,  $\delta \in S$ . What we demand is  $(G^{<\delta>})$  - see before Fact A):

- (\*)<sub>2</sub> letting  $H^{<\delta>} = \{x \in H_{\delta+1} : \mathbf{h}_{\delta+1}(x) \in G^{<\delta>}\}$ , if  $s^* = g_\delta(x_{\beta_\delta}) \in \mathbb{Z} \setminus \{0\}$  ( $g_\delta$  from 4.2), then there is no homomorphism  $f_\delta : G^{<\delta>} \rightarrow H^{<\delta>}$  such that
- ( $\alpha$ )  $f_\delta(x_{\beta_{\zeta, i}^\delta}) - \mathbf{k}_\delta(x_{\beta_{\zeta, i}^\delta}) \in \mathbb{Z}$  is the same for all  $i \in (\bigcup_{\varepsilon < \zeta} \lambda_\varepsilon, \lambda_\zeta]$
- ( $\beta$ )  $\mathbf{h}_{\delta+1} \circ f_\delta = \text{id}_{G^{<\delta>}}$ .

[Why is this possible? By non-Whiteheadness of  $G^\sigma / \bigcup_{i < \sigma} G^i$  that is see  $(d)(\gamma)^-$  in

4.1.]

The rest should be clear.

*Proof of 4.1(2).* Of course, similar to that of 4.1(1) but with some changes.

Step A: Without loss of generality there is a homomorphism  $f^*$  from  $\bigcup_{i < \sigma} G^i$  to  $\mathbb{Z}$

which cannot be extended to a homomorphism from  $G_\sigma$  to  $\mathbb{Z}$ .

[Why? Standard, see [Fu].]

Step B: During the construction of  $G^*$ , we choose  $G_\alpha^*$  by induction on  $\alpha \leq \kappa$ , but if  $h_\delta^*(0)$  from 4.2 is a member of  $G_\delta^*$  in (\*)<sub>1</sub> we replace  $(x_{\beta_{\zeta, \gamma}^\delta} - x_{\gamma_{\lambda_\zeta}^\delta})$  by  $(x_{\beta_{\zeta, \gamma}^\delta} - x_{\beta_{\lambda_\zeta}^\delta} + f^*(t_{\gamma, \zeta}^{\zeta+1})g_\delta(0))$ , note that  $f^*(t_{\gamma, \zeta}^{\zeta+1}) \in \mathbb{Z}$  and  $h_\delta^*(0) \in G_\delta^*$ .

So if in the end  $f : G^* \rightarrow \mathbb{Z}$  is a non-zero homomorphism, let  $x^* \in G^*$  be such that

$f(x^*) \neq 0$  and<sup>5</sup>  $|f^*(x^*)|$  is minimal under this, so without loss of generality it is 1. Hence for some  $\delta \in S$  we have:

- (\*)<sub>3</sub>  $f(g_\delta(0)) = 1_{\mathbb{Z}}$
- (\*)<sub>4</sub>  $f(x_{\gamma_{\lambda_\zeta+1+1+\gamma}}^\delta) = f(x_{\gamma_{\lambda_\zeta}}^\delta)$  for  $\gamma \in \lambda_{\zeta+1} \setminus \lambda_\zeta$   
that is  $f(x_{\beta_{\zeta,\gamma}}^\delta) = f(x_{\lambda_{\zeta \text{ eta}}}^\delta)$

(in fact this holds for stationarily many ordinals  $\delta \in S$ ).

So we get an easy contradiction.

3) The proof is included in the proof of part (2). □<sub>4.1</sub>

We also note the following consequence of a conclusion of an instance of GCH.

**4.3 Claim.** *Assume*

- (a)  $\lambda = \mu^+$  and  $\mu > \sigma = cf(\mu)$
- (b)  $\lambda = \lambda^\theta$  where  $\theta = 2^\sigma$   
(equivalently  $\mu^\theta = \mu^+ > 2^\theta$ )
- (c)  $S \subseteq \{\delta < \lambda : cf(\delta) = \sigma\}$  is stationary
- (d)  $\bar{\eta} = \langle \eta_\delta : \delta \in S \rangle$  with  $\eta_\delta$  an increasing sequence of length  $\sigma$  with limit  $\delta$ .

Then we can find  $\langle \bar{A}^\delta : \delta \in S \rangle$  such that:

- (α)  $\bar{A}^\delta = \langle A_i^\delta : i < \sigma \rangle$
- (β)  $A_i^\delta \in [\delta]^{<\mu}$  and  $\sup(A_i^\delta) < \delta$
- (β)<sup>+</sup> for some  $\langle \lambda_i^* : i < \sigma \rangle$  increasing with limit  $\lambda$ ,  $|A_i^\delta| < \lambda_i^*$ ,
- (γ) for every  $h : \lambda \rightarrow \lambda$ , for stationarily many  $\delta \in S$  we have  $(\forall i < \sigma)[h(\eta_\delta(i)) \in A_i^\delta]$ .

*4.4 Remark.* 1) We can restrict ourselves to  $h : \lambda \rightarrow \mu$  in clause (γ), and then, of course, can use  $\langle A_i^\delta : i < \sigma : \delta \in S \rangle$  with  $A_i^\delta \subseteq \mu$ .

2) We can add to the conclusion “ $A_i^\delta \subseteq \eta_\delta(i+1)$ ” if  $\bar{\eta}$  guess clubs.

*Proof.* Let  $\langle \lambda_i : i < \sigma \rangle$  be increasing continuous with limit  $\mu$ . Let  $\langle \bar{\alpha}_\gamma : \gamma < \lambda \rangle$  list  ${}^\theta \lambda$ , so  $\bar{\alpha}_\gamma = \langle \alpha_{\gamma,\varepsilon} : \varepsilon < \theta \rangle$  and without loss of generality  $\alpha_{\gamma,\varepsilon} \leq \gamma$ . For each  $\delta \in S$  let  $\langle b_i^\delta : i < \sigma \rangle$  be an increasing continuous sequence of subsets of  $\delta$  with union  $\delta$  such that  $|b_i^\delta| < \mu$  and  $\sup(b_i^\delta) < \delta$ ; for (β)<sup>+</sup>, moreover  $|b_i^\delta| \leq \lambda_i$ ;

---

<sup>5</sup>What does this mean?  $f^*(x^*)$  is an integer so its absolute value is well defined

this is possible as  $\text{cf}(\delta) = \sigma = \text{cf}(\mu) < \mu$ . Let  $\langle g_\varepsilon : \varepsilon < \theta \rangle$  list  ${}^\sigma\sigma$  and define  $A_i^{\varepsilon, \delta} =: \{\alpha_{\gamma, \varepsilon} : \gamma \in b_{g_\varepsilon(i)}^\delta\}$ . Now  $A_i^{\varepsilon, \delta}$  is a set of cardinality  $\leq |b_{g_\varepsilon(i)}^\delta| < \mu$  and  $\text{sup}(A_i^{\varepsilon, \delta}) \leq \text{sup}(b_{g_\varepsilon(i)}^\delta)$  (as we have demanded that  $\alpha_{\gamma, \varepsilon} \leq \gamma$ ) but  $\text{sup}(b_{g_\varepsilon(i)}^\delta) < \delta$  by the choice of the  $b_j^\delta$ 's hence  $\text{sup}(A_i^{\varepsilon, \delta}) < \delta$ . So for each  $\varepsilon < \theta$  the sequence  $\bar{\mathbf{A}}^\varepsilon =: \langle \bar{A}^{\varepsilon, \delta} : \delta \in S \rangle$ , where  $\bar{A}^{\varepsilon, \delta} = \langle A_i^{\varepsilon, \delta} : i < \sigma \rangle$  satisfies clauses  $(\alpha) + (\beta)$  and  $(\beta)^+$  when relevant. Hence it suffices to prove that for some  $\varepsilon < \theta$  the sequence  $\bar{\mathbf{A}}^\varepsilon$  satisfy clause  $(\gamma)$ , too. Assume toward contradiction that for every  $\varepsilon < \theta$  the sequence  $\bar{\mathbf{A}}^\varepsilon$  fails clause  $(\gamma)$  hence there is  $h_\varepsilon : \lambda \rightarrow \lambda$  which exemplifies this, that is for some club  $E_\varepsilon$  of  $\lambda$ ,  $\delta \in E_\varepsilon \cap S \Rightarrow (\exists i < \sigma)[h_\varepsilon(\eta_\delta(i)) \notin A_i^{\varepsilon, \delta}]$ . So for every  $\beta < \lambda$  the sequence  $\langle h_\varepsilon(\beta) : \varepsilon < \theta \rangle$  belongs to  ${}^\theta\lambda$ , hence is equal to  $\bar{\alpha}_{h(\beta)}$  for some  $h(\beta) < \lambda$ . Clearly  $E = \{\delta < \lambda : \delta \text{ a limit ordinal and } (\forall \beta < \delta)h(\beta) < \delta\}$  is a club of  $\lambda$  (recall  $\theta < \lambda$ ) hence we can find  $\delta(*) \in E \cap S$ . We define  $g^* : \sigma \rightarrow \sigma$  by  $g^*(i) = \text{Min}\{j < \sigma : h(\eta_{\delta(*)}(j)) \in b_j^\delta\}$ , now  $g^*$  is well defined as, for  $i < \sigma$  the ordinal  $h(\eta_{\delta(*)}(i))$  is  $< \delta(*)$  (as  $\delta(*) \in E$ ) and  $\eta_{\delta(*)}(i) < \delta(*)$  and  $\delta = \bigcup_{j < \sigma} b_j^\delta$ . As

$g^* \in {}^\sigma\sigma$  clearly for some  $\varepsilon(*) < \theta$  we have  $g_{\varepsilon(*)} = g^*$ .

So, for any  $i < \sigma$  let  $\gamma_i = h(\eta_{\delta(*)}(i))$ , now  $h(\eta_{\delta(*)}(i)) \in b_{g^*(i)}^\delta$  (by the choice of  $g^*$ ) and  $g^*(i) = g_{\varepsilon(*)}(i)$  by the choice of  $\varepsilon(*)$ , together  $\gamma_i \in b_{g_{\varepsilon(*)}(i)}^\delta$ . But  $A_i^{\varepsilon(*), \delta(*)} = \{\alpha_{\gamma, \varepsilon(*)} : \gamma \in b_{g_{\varepsilon(*)}(i)}^\delta\}$  by the choice of  $A_i^{\varepsilon(*), \delta(*)}$  hence  $\alpha_{\gamma_i, \varepsilon(*)} \in A_i^{\varepsilon(*), \delta(*)}$ , but as  $\gamma_i = h(\eta_{\delta(*)}(i))$ , by the choice of  $h$  we have  $h_{\varepsilon(*)}(\eta_{\delta(*)}(i)) = \alpha_{\gamma_i, \varepsilon(*)} \in A_i^{\varepsilon(*), \delta(*)}$ .

So  $(\forall i < \sigma)(h_{\varepsilon(*)}(\eta_{\delta(*)}(i)) \in A_i^{\varepsilon(*), \delta(*)})$ , which by the choice of  $h_\varepsilon$  implies  $\delta(*) \notin E_{\varepsilon(*)}$  but  $\delta(*) \in E \subseteq \bigcap_{\varepsilon < \theta} E_\varepsilon$ , contradiction. □<sub>4.3</sub>
