GENERAL NON-STRUCTURE THEORY
E59

SAHARON SHELAH

Abstract. The theme of the first two sections, is to prepare the framework of how from a “complicated” family of so called index models $I \in K_1$ we build many and/or complicated structures in a class $K_2$. The index models are characteristically linear orders, trees with $\kappa + 1$ levels (possibly with linear order on the set of successors of a member) and linearly ordered graphs, for this we phrase relevant complicatedness properties (called bigness).

We say when $M \in K_2$ is represented in $I \in K_1$. We give sufficient conditions when $\{M_I : I \in K_1^\lambda\}$ is complicated where for each $I \in K_1^\lambda$ we build $M_I \in K_2$ (usually $\in K_2^\lambda$) represented in it and reflecting to some degree its structure (e.g. for $I$ a linear order we can build a model of an unstable first order class reflecting the order). If we understand the structures in $K_2$ well enough we can even build, e.g. rigid members of $K_2^\lambda$.

Note that we mention “stable”, “superstable”, but in a self contained way, not relying in any way on stability theory, just using an equivalent definition which is useful here and explicitly given. We also frame the use of generalizations of Ramsey and Erdős-Rado theorems to get models in which any $I$ from the relevant $K_1$ is reflected. We give in some detail how this may apply to specific cases: Boolean Algebras, the class of separable reduced Abelian $\hat{\mathbb{p}}$-group and how we get relevant models for ordered graphs (in some cases via forcing).

In the third section we show stronger results concerning linear orders. If for each linear order $I$ of cardinality $\lambda > \aleph_0$ we can attach a model $M_I \in K_\lambda$ in which the linear order can be embedded such that for enough cuts of $I$, their being omitted is reflected in $M_I$, then there are $2^\lambda$ non-isomorphic cases.

But in the end of the second section we show how the results on trees with $\omega + 1$ levels (on which concentrate [Sh:331]) gives results on linear ordered (not covered by §3), on trees with $\omega + 1$ levels see [Sh:331]. To get more we prove explicitly more on such trees. Those will be enough for results in model theory of Banach space of Shelah-Usvyatsov [ShUs:928], see more in [Sh:E81].

Key words and phrases. model theory, set theory, non-structure, number of non-isomorphic models, unstable theories, linear orders, EM-models.

The author thanks Alice Leonhardt for the beautiful typing. This is a revised version of [Sh:300, Ch.III,§1-§3], has existed (and somewhat revised) for many years. Was mostly ready in the early nineties, and public, to some extent. For the sake of [Sh:331], we add the part of §1 from [FaSh:954]. For the sake of [Sh:300, Ch.II,§1-§3], we add in the end of §2. Recently this work was used and continued in Farah-Selah [FaSh:954]. This was written as Chapter III of the book [Sh:e], which hopefully will materialize some day, but in meanwhile it is [Sh:331]. The intentions were [Sh:331] (revising [Sh:331] for Ch.I, §1-§3, for Ch.II, §1-§3, for Ch.III, §1-§3, for Ch.IV, §1-§3, for Ch.V, §1-§3, for Ch.VI, §1-§3, for Ch.VII, §1-§3, for Ch.VIII, §1-§3, for the appendix, and probably [Sh:757] and [Sh:384], for the appendix, and probably [Sh:757] and [Sh:384], and maybe [Sh:800], and [Sh:384]). References like [Sh:331, q17=Lc2] means that q17 will only help the author if changes in the paper [Sh:331] will change the number. The reader should note that the version in my website is usually more updated than the one in the mathematical archive.

§ 0. Introduction

A major result presented in this paper is (in earlier proofs we have it only in “most” cases):

**Theorem 0.1.** If $\psi \in L_{\chi, \omega}, \varphi(\bar{x}, \bar{y}) \in L_{\chi, \omega}, \ell g(\bar{x}) = \ell g(\bar{y}) = \partial$ and $\psi$ has the $\varphi(\bar{x}, \bar{y})$ order property (see Definition 3.2(5)) then $I(\lambda, \psi) = 2^\lambda$ provided that for example:

- $\lambda \geq \chi + N_1, \partial < R_0$ or $\lambda > \chi + \partial + N_1$ or $\lambda^+ < 2^\lambda, \lambda \geq \chi$.

**Proof.** By $\text{t23} 3.41(2)$, clause (b) of $\text{t23} 3.41(2)$ holds. When $\lambda \geq \chi + N_1, \partial < R_0$, by Theorem 1.25(3), $I(\lambda, \psi) = 2^\lambda$.

So we can assume that $\lambda \geq \chi$ and $\partial \geq R_0$. When $\lambda^+ = \lambda$ or $\lambda(\partial^+) < 2^\lambda$ the conclusion holds by $\text{t23} 3.29(a), \text{t23} 3.29(b)$, respectively, using $\kappa = \partial^+$ and the existence of such models follows from $\text{t23} 3.41(2)$, see (b) there, they are as required by $\text{t23} 3.41(4)$. When $\lambda > \chi + \partial^+$ the conclusion holds by $\text{t23} 3.41(1)$. So we are done. $\square$

Note that although some notions connected to stability appear, they are not used in any way which require knowing them: we define what we use and at most quote some results. In fact, the proof covered problems with no (previous) connection to stability. For understanding and/or checking, the reader does not need to know the works quoted below: they only help to see the background. Also the citation to $\text{Sh:309}$, $\text{Sh:331}$, $\text{Sh:511}$ are just to point additional information, and are not needed for understanding.

Generally the strategy here is the construction of many models (up to isomorphism in this paper) in $K_\lambda := \{ M \in K : \| M \| = \lambda \}$ goes as follows. We are given a class $K$ of models (with fixed vocabulary), and we are trying to prove that $K$ has many complicated members. To help us, we have a class $K^1$ of "index models" (this just indicates their role; supposedly they are well understood; they usually are a class of linear orders or a class of trees). By the "non-structure property of $K^1$", for some formulas $\varphi_\ell$ (see below), for every $I \in K^1_\lambda$ there is $M_I \in K_\lambda$ and $\bar{a}_I \in M_I$ for $t \in I$, which satisfies (in $M_I$) some instances of $\pm \varphi_\ell$.

We may demand on $M_I$:

- (0) nothing more (except the restriction on the cardinality), or
- (1) $\langle \bar{a}_t : t \in I \rangle$ behaves nicely: like a skeleton (see $\text{t23} 1(1)$), or even
- (2) $M_I$ is “embedded” in a model built from $I$ in a simple way ($\Delta$–represented; see Definition 1.8), or
- (3) $M_I$ is built from $I$ in a simple way, an the extreme case being $E_{\text{EM}}(I, \Phi)$; see Definition 1.8 where $\tau = \tau(M_I)$ of course.

Now even for (0) we can have meaningful theorems (see $\text{Sh:309}, a2$ and $\text{Sh:309}, 1.3$); but we cannot have all we would naturally like to have — see $\text{Sh:309}, b17$ (i.e., we cannot prove much better results in this direction, as shown by a consistency proof).

Though it looks obvious by our formulation, experience shows that we must stress that the formulas $\varphi_\ell$ need not be first order, they just have to have the right vocabulary (but in results on “no $M_i$ embeddable in $M_j$” this usually means...
embedding preserving $\pm \varphi$ (but see [Sh:32]). So they are just properties of sequences in the structures we are considering preserved by the morphism we have in mind.

Another point is that though it would be nice to prove $[I \not\cong J \Rightarrow M_I \not\cong M_J]$; this does not seem realistic. What we do is to construct a family 

$$\{I_\alpha : \alpha < 2^\lambda\} \subseteq K^1_\lambda$$

such that for $\alpha \neq \beta$, in a strong sense $I_\alpha$ is not isomorphic to (or not embeddable into) $I_\beta$ (see [E59], more in [Sh:351], a2, [Sh:351], 1.32), such that now we have $M_I, M_J$ not isomorphic for $\alpha \neq \beta$. We are thus led to the task of constructing such $I_\alpha$'s, which, probably unfortunately, splits to cases according to properties of the cardinals involved. Sometimes we just prove $\{\alpha : M_\alpha \cong M_\beta\}$ is small for each $\beta$.

A point central to [Sh:E58], [Sh:421], [Sh:511], [Sh:384] and [Sh:482] but incidental here, is the construction of a model which is for example rigid or has few endomorphisms, etc. This is done in details in §15-17 in §2D for Boolean Algebras (and for many relatives of “rigid” and classes of Boolean Algebras, in [Sh:136] and better and more in [Sh:511]).

The methods here can be combined with [Sh:220] or [Sh:188] to get non-isomorphic $L_{\infty, \lambda}$-equivalent models of cardinality $\lambda$: Instead of “$L_{\infty, \lambda}$-equivalent non-isomorphic model of $T$” we can consider equivalence by stronger games, e.g. $EF_{\alpha, \lambda}$-equivalence started in Hyttinen-Tuuri [HyTu91], and then Hyttinen-Shelah [HySh:474], [HySh:529], [HySh:602]; See Vaananen [Vaa95] on such games and for more (in the 2010-th), see [Sh:897].

In the next few paragraphs we survey the results of this paper. In this survey we omit some parameters for various defined notions. These parameters are essential for an accurate statement of the theorems. We suppress them here trying to make the reading easier while still communicating essential points.

Classically Ehrenfeucht Mostowski model of a theory $T$, are ones generated by an indiscernible sequence $\langle a_t : t \in I \rangle$ for $I$ a linear order which are models of some $T_1 \supseteq T$ with Skolem functions. In §1 we deal with a generalization, $I$ not necessary a linear order so write $GEM(I, \Phi)$. This is how in a natural way we construct a model from an “index model”. The proof of existence many times rely on partition theorems. We give definitions, deal with the framework, quote important cases, and present general theorems for getting the GEM models, i.e., getting templates; we then, as an example, deal with random graphs for theories in $L_{\kappa^+, \omega}$.

In §2 we discuss a more general method of so called “representability” (from [Sh:136]). This is a natural way to get for “a model gotten from an index model $I$” that “$I$ is complicated” implies “$M$ is complicated”. We discuss applications (to separable reduced Abelian $p$-groups and to Boolean algebras), but the aim is to explain; full proofs of fuller results will appear later (see [Sh:351], §3, [Sh:511] respectively). We introduce two strongly contradictory notions, the $\Delta$–representability of a structure $M$ in the “free algebra” (i.e., “polynomial algebra”) of an index model (Definition [E59]) and the $\varphi(x, y)$–unembeddability of one index model in another. Now, to show that a class $K$ has many models it suffices if for some formula $\varphi$, one first shows that:
(a) an index class $K_1$ has many pairwise $\varphi$–unembeddable structures, second, that

(b) for each $I \in K_1$, there is a suitable model $M_I$ which is $\Delta$–representable in the free algebra on $I$, which in some sense reflects the structure $I$ and finally that

(c) if $M_I \equiv M_J$ or just $M_I$ is embeddable into $M_J$ and $M_J$ is $\Delta$–representable in the free algebras on $J$ then $I$ is $\varphi$–embeddable in $J$.

However, for building for example a rigid model of cardinality $\lambda$, it is advisable to use $\langle I_\alpha : \alpha < \lambda \rangle$ such that $I_\alpha$ is $\varphi$–unembeddable into $\sum_{\beta < \alpha} I_\beta$. (See §§16, 17, 26, 27.) Generally having a suitable sequence of $I \in K_1$ is expressed by “$K_1$ has a suitable bigness property”. Note that from having “many complicated $I \in K_1^\kappa$ (tree with say $\kappa$ levels)” we can deduce such existence for the class of linear order, see §27.

Now, §3 does not depend on §2. The point is that in this section our non-embeddings proofs are so strong that they do not need even “representability”, we use a much weaker property. In §3 we extend and simplify the argument showing that an unstable first order theory $T$ has $2^\lambda$ models of cardinality $\lambda$ if $\lambda \geq |T| + \aleph_1$. Rather than constructing Ehrenfeucht–Mostowski models we consider a weaker notion — that of a linear order $J$ indexing a weak $(\kappa, \varphi)$–skeleton like sequence in a model $M$. In this section, $K_1$ is the class of linear orders. The formula $\varphi(x, y)$ need not be first order and after §25 may have infinitely many arguments. Most significantly we make no requirement on the means of definition of the class $K$ of models (for example first order, $L_{\infty, \infty}$, etc). We require only that for each linear order $J$ there is an $M_J \in K$ and a sequence $\langle a_s : s \in J \rangle$ which is weakly $(\kappa, \varphi)$–skeleton like in $M_J$.

Ehrenfeucht and Mostowski [Ehr56, GrMo56] built what are here GEM$_n(L, \varnothing, \Phi)$ for $I$ a linear order and first order $T$ where $\tau = \tau_T$. Ehrenfeucht [Ehr57, Eh58] (and Hodges in [Hod73] improved the set theoretic assumption) proved that if $T$ has the property $(E)$ then it has at least two non-isomorphic models (this property is a precursor of being unstable).

Recall that the property $(E)$ says that: some formula $R(x_1, \ldots, x_n)$ is asymmetric on some infinite subset of some model of $T$; note that $(E)$ is not equivalent to being unstable as the theory of random graphs fails it. Morley [Mor65] proves that for well ordered $I$, the model generated by $I$ is stable in appropriate cardinalities, to deduce that non-totally transendental countable theories are not categorical in any $\lambda > \aleph_0$. See more in [Sh:c, VII, VIII]; by it if $T \subseteq T_1$ are unstable, complete first order and $\lambda \geq |T_1| + \aleph_1$ then $T_1$ has $2^\lambda$ models of cardinality $\lambda$ with pairwise non-isomorphic reducts to $\tau_T$. On the cases for $L_{\omega_1, \omega}, \lambda > \chi$, see Grossberg-Shelah [GSh:222, GSh:299] which continue [Sh:T1].

This paper is a revised version of sections §1, §2, §3 of chapter III of [Sh:300]. Meanwhile see recent works of Will Boney and Malliaris-Shelah [MiSh:1149].

In the intended book on non-structure, this was suppose to be Ch. III. For later chapters §2 is essential to some of the later parts of non-structure (see [Sh:309], [Sh:331] then but not §1 or §3 still but better read §§4, 5. This work is continued in [Sh:E81].
We thank the referee for many suggestions to improve the presentation.

§ 0(A). Preliminaries.

Notation 0.2. 1) We use $\mathcal{L}$ to denote a logic, $\tau$ to denote a vocabulary (i.e. a set of predicates and function symbols).

2) A language $L$ is a set of sentences (and formulas, e.g. $\mathcal{L}(\tau)$, see Definition 0.5 below).

3) For a model $M$, $\tau(M) = \tau_M$ is the vocabulary of $M$.

4) $\mathbb{L}$ is first order logic, $\mathbb{L}_{\lambda,\kappa}$ is like first order logic allowing $\bigwedge_{i<\alpha} \psi_i$, $(\exists \bar{x}_{[u]})(\psi)$, where $\bar{x}_{[u]} = \langle x_i : i \in u \rangle$, $|u| < \kappa, \alpha < \lambda$.

Definition 0.3. 1) A logic $\mathcal{L}$ consists of:

(a) a class function, giving for every vocabulary $\tau$ a language $L = \mathcal{L}(\tau) = L_\tau$, i.e. a set of sentences and formulas $L$ and naturally defined formula $L$ will denote such language or just a set of formulas (usually with some closure properties)

(b) a satisfaction relation $\models \mathcal{L}$ such that $M \models L \psi$ implies $M$ is a model, $\psi \in \mathcal{L}(\tau_M)$

(c) if $M_1, M_2$ are isomorphic $\tau$-models and $\psi \in \mathcal{L}(\tau)$ then $M_1 \models \psi \iff M_2 \models \psi$. 
§ 1. Models from Indiscernibles

§ 1(\Lambda). Background.

We survey here [Sh:a, Ch.VIII.\S 3] (already in [Sh:a]), which was the starting point for the other works appearing or surveyed in this paper and [Sh:363], [Sh:309]. So we concentrate on building many models for first order theories, using G.E.M. models, i.e., in all respects taking the easy pass. Our aim there was

Theorem 1.1. If \( T \) is a complete first order theory, unstable and \( \lambda \geq |T| + \aleph_1 \), then \( \hat{I}(\lambda, T) = 2^\lambda \).

(This is reproved here in \( \S 17 \)) where

Definition 1.2. A first order theory \( T \) is unstable when for some first order formula \( \varphi(\bar{x}, \bar{y}) (n = \ell g(\bar{x}) = \ell g(\bar{y})) \) in the vocabulary \( \tau_T \) of \( T \) of course, for every \( \lambda \) there is a model \( M \) of \( T \) and \( \bar{a}_i \in M \) for \( i < \lambda \) such that

\[ M \models \varphi[\bar{a}_i, \bar{a}_j] \text{ if } i < j (i < \lambda). \]

Definition 1.3. For a theory \( T \) and vocabulary \( \tau \subseteq \tau_T \), let

\[ \hat{I}(\lambda, T) = \text{the number of models of } T \text{ of cardinality } \lambda, \text{ up to isomorphism}, \]

\[ \hat{I}_\tau(\lambda, T) = \text{the number of } \tau \text{-reducts of models of } T \text{ of cardinality } \lambda, \text{ up to isomorphism}. \]

Definition 1.4. 1) For a class \( K \) of models and a set \( \Delta \) of formulas:

\[ \hat{I}(\lambda, K) = \text{the number of models in } K \text{ of cardinality } \lambda \text{ up to isomorphism}, \]

\[ \hat{I}(\lambda, K) = \text{the number of models in } K \text{ up to isomorphism}, \]

\[ \hat{I}_\Delta(\lambda, K) = \sup \{ \mu : \text{there are } M_i \in K, \text{ for } i < \mu, \text{ such that for } i \neq j \text{ there is no } \Delta \text{-embedding of } M_i \text{ to } M_j \}. \]

see part (2); and we may write \( \tau \) instead \( \Delta = L(\tau_K) \), may omit \( \tau \) and \( \Delta \) when it is \( L(\tau_M) \).

2) \( f : M \to N \) is a \( \Delta \)-embedding (of \( M \) into \( N \)) when \( (f \text{ is a function from } |M| \text{ into } |N| \text{ and}) \) for every \( \varphi(\bar{x}) \in \Delta \) and \( \bar{a} \in Lg(\bar{a})|M| \), we have:

\[ M \models \varphi[\bar{a}] \Rightarrow N \models \varphi[f(\bar{a})]. \]

(so if \( (x \neq y) \in \Delta \) then \( f \) is one to one).

Definition 1.5. 1) A sentence \( \psi \in L_{\lambda^+, \aleph_0} \) is \( \partial \)-unstable when there are \( \alpha < \partial \) and a formula \( \varphi(\bar{x}, \bar{y}) \) from \( L_{\lambda^+, \aleph_0} \) with \( \ell g(\bar{x}) = \ell g(\bar{y}) = \alpha \) such that \( \psi \) has the \( \varphi \)-order property, i.e., for every \( \lambda \) there is a model \( M_\lambda \) of \( \psi \) and a sequence \( \bar{a}_\zeta \) of length \( \alpha \) from (i.e. of elements of) \( M_\lambda \) such that for \( \zeta, \xi < \lambda \) we have:

\[ M_\lambda \models \varphi[\bar{a}_\zeta, \bar{a}_\xi] \Leftrightarrow \zeta < \xi. \]

If \( \partial = \aleph_0 \) we may omit it.

2) For \( \kappa \) regular and \( T \) first order, we say \( \kappa < \kappa(T) \) when there are first order formulas \( \varphi_i(\bar{x}, \bar{y}_i) \in L(\tau_T) \) for \( i < \kappa \) and for every \( \lambda \) there is a model \( M_\lambda \) of \( T \) and for \( i \leq \kappa, \eta \in i^\lambda \) a sequence \( \bar{a}_\eta \) from \( M_\lambda \), with
\[ \forall i < \kappa \Rightarrow \ell g(\bar{a}_n) = \ell g(\bar{y}_i) \]

\[ \forall i = \kappa \Rightarrow \ell g(\bar{a}_n) = \ell g(\bar{x}) \]

such that: if \( \nu \in ^1 \lambda, \eta \in ^1 \lambda, \nu < \eta \) then \( M_\lambda \models \varphi_{\nu+1}[\bar{a}_\eta, \bar{a}_{\nu^*(\alpha)}] \Leftrightarrow \eta(\bar{x}) = \alpha. \) [We shall not use this except in §1(B) below.]

3) \( T, \) a first order theory, is unsuperstable if \( \aleph_0 < \kappa(T) \) [but we shall use it only in §1(B)].

§ 1(B). GEM models.

**Definition 1.6.** 1) \( \bar{a}_i : t \in I \) is \( \Delta \)-indiscernible (in \( M \)) when

(a) \( I \) is an index model (usually linear order or tree), i.e., it can be any model but its role will be as an index set,

(b) \( \Delta \) is a set of formulas in the vocabulary of \( M \) (i.e. in \( L_{\tau(M)} \) for some logic \( L \))

(c) the \( \Delta \)-type in \( M \) of \( \bar{a}_0 \cdot \ldots \cdot \bar{a}_{n-1} \) for any \( n < \omega \) and \( t_0, \ldots, t_{n-1} \in I \) depends only on the quantifier free type of \( \langle t_0, \ldots, t_{n-1} \rangle \) in \( I \).

• Recall that the \( \Delta \)-type of \( \bar{a} \) in \( M \) is \( \{ \varphi(\bar{x}) \in \Delta : M \models \varphi(\bar{a}) \} \), where \( \bar{a}, \bar{x} \) are indexed by the same set. So the length of \( \bar{a}_i \) depend just on the quantifier free type which \( \ell g(\bar{a}_i) \) realizes in \( I \).

• When \( \Delta \) is closed under negations for any \( \varphi(\bar{x}) \) we have \( \varphi(\bar{x}) \) belongs or \( \neg \varphi(\bar{x}) \).

• If we allow \( \varphi(\bar{x}) \in \Delta, \kappa > \alpha = \ell g(\bar{x}) \geq \omega \) and we allow \( \langle t_i : i < \alpha \rangle \) above, then we say \( (\Delta, \kappa) \)-indiscernible.

2) For a logic \( L, \) “\( L \)-indiscernible” will mean \( \Delta \)-indiscernible for \( L_{\tau(M)} \), the set of \( L \)-formulas in the vocabulary of \( M \). If \( \Delta, L \) are not mentioned we mean first order logic.

3) Notation: Remember that if \( t = \langle t_i : i < \alpha \rangle \) then \( \bar{a}_t = \bar{a}_{t_0} \cdot \bar{a}_{t_1} \cdot \ldots \).

Many of the following definitions are appropriate for counting the number of models in a pseudo elementary class. Thus, we work with a pair of vocabularies, \( \tau \subseteq \tau_1 \). Often \( \tau_1 \) will contain Skolem functions for a theory \( T \) which is \( \subseteq \mathcal{L}(\tau) \).

**Convention 1.7.** For the rest of this section all predicates and function symbols have finite number of places (and similarly \( \varphi(\bar{x}) \) means \( \ell g(\bar{x}) < \omega \).

**Definition 1.8.** 1) \( M = \text{GEM}(I, \Phi) \) when, for some vocabulary \( \tau = \tau_\Phi = \tau(\Phi) \) (called \( L_{\tau_1}^* \) in [Sh:c, Ch.VII]) and sequences \( \bar{a}_t (t \in I) \) we have:

(i) \( M \) is a \( \tau_\Phi \)-structure and is generated by \( \{ \bar{a}_t : t \in I \} \),

(ii) \( \langle \bar{a}_t : t \in I \rangle \) is quantifier free indiscernible in \( M \),

(iii) \( \Phi \) is a function, taking (for \( n < \omega \)) the quantifier free type of \( \bar{t} = \langle t_0, \ldots, t_{n-1} \rangle \) in \( I \) to the quantifier free type of \( \bar{a}_t = \bar{a}_t_0 \cdot \ldots \cdot \bar{a}_t_{n-1} \) in \( M \) (so \( \Phi \) determines \( \tau_\Phi \) uniquely).
1A) Pedantically we should say $\tilde{a} = \langle \tilde{a}_t : t \in I \rangle$ is a witness for $M = \text{GEM}(I, \Phi)$ or $(M, \tilde{a})$ is a $\text{GEM}(I, \Phi)$ pair when the above holds, but abusing notation we usually write $M$ instead of $(M, \tilde{a})$.

1B) If $\tau \subseteq \tau_{\phi}$ let $\text{GEM}_{\tau}(I, \Phi)$ be the $\tau$-reduct of $\text{GEM}(I, \emptyset)$.

2) A function $\Phi$ as above is called a template and we say it is proper for $I$ when there is $M$ such that $M = \text{GEM}(I, \Phi)$. We say $\Phi$ is proper for $K$ if $\Phi$ is proper for every $I \in K$, and lastly $\Phi$ is proper for $(K_1, K_2)$ if it is proper for $K_1, \tau(K_2) \subseteq \tau_{\phi}$ and $\text{GEM}_{\tau(K_2)}(I, \Phi) \in K_2$ for $I \in K_1$.

3) For a logic $\mathcal{L}$, or even a set $\mathcal{L}$ of formulas in the vocabulary of $M$, we say that $\Phi$ is almost $\mathcal{L}$-nice (for $K$) when it is proper for $K$ and:

\begin{itemize}
  \item[(*)] for every $I \in K$, $\langle \tilde{a}_t : t \in I \rangle$ is $\mathcal{L}$-indiscernible in $\text{GEM}(I, \Phi)$.
  \item[(**) ] for $J \subseteq I$ from $K$ we have $\text{GEM}(J, \Phi) \prec_{\mathcal{L}} \text{GEM}(I, \Phi)$.
\end{itemize}

4) In part (3), $\Phi$ is $\mathcal{L}$-nice when it is almost $\mathcal{L}$-nice and

\begin{itemize}
  \item[(***)] for $J \subseteq I$ from $K$ we have $\text{GEM}_{\tau}(J, \Phi) \prec_{\mathcal{L}} \text{GEM}_{\tau}(I, \Phi)$.
\end{itemize}

5) In part (3) we say that $\Phi$ is $(\mathcal{L}, \tau)$-nice when $\tau \subseteq \tau_{\phi}$, it is almost $\mathcal{L}$-nice and (see $\mathfrak{b}_{17}$, (1))

\begin{itemize}
  \item[(** * )] for $I \subseteq J$ from $K$ we have $\text{GEM}_{\tau}(J, \Phi) \prec_{\mathcal{L}} \text{GEM}_{\tau}(I, \Phi)$.
\end{itemize}

In the book [Sh:c], always $L(\tau_{\phi})$-nice $\Phi$ were used and $\text{GEM}(I, \Phi), \text{GEM}_{\tau}(I, \Phi)$ here are $\text{EM}(I, \Phi), \text{EM}(I, \Phi)$ there.

**Definition 1.9.** 1) Saying “a GEM-model” will mean “a model of the form $\text{GEM}_{\tau}(I, \Phi)$” where $\Phi, I, \tau$ are understood from the context.

2) We identify $I \subseteq \kappa \geq \lambda$ which is closed under initial segments, with the model $(I, P_{\alpha}, \cap, \kappa, <_{lx}, <_{x})_{\alpha < \kappa}$, where:

$P_{\alpha} = I \cap \alpha \lambda$,

$\rho = \eta \cap \nu$ if $\rho = \eta[\alpha]$ for the maximal $\alpha$ such that $\eta[\alpha] = \nu[\alpha]$,

$<_{lx}$ being initial segment of (including equality),

$<_{x}$ the lexicographic order.

3) Similarly to (2), for any linear order $J$, every $I \subseteq \kappa \geq J$ which is closed under initial segments is identified with $(I, P_{\alpha}, \cap, <_{lx}, <_{x})_{\alpha < \kappa}$ ($<_{lx}$ is still well defined).

4) $K_{\text{tr}}$ is the class of such models, i.e., models isomorphic to such $I$, i.e., to $(I, P_{\alpha}, \cap, <_{lx}, <_{x})_{\alpha < \kappa}$ for some $I \subseteq \kappa \geq J$ which is closed under initial segments, $J$ a linear order (tr stands for tree). We call $I$ standard if $J$ is an ordinal or at least well ordered.

5) $K_{\text{ar}}$ is the class of linear orders.

**Remark 1.10.** The main case here is $\kappa = \aleph_{0}$. We need such trees for $\kappa > \aleph_{0}$, for example if we would like to build many $\kappa$-saturated models of $T$, $\kappa(T) > \kappa$, $\kappa$ regular. If $\kappa(T) \leq \kappa$ there may be few $\kappa$-saturated models of $T$.

In [Sh:c, Ch.VIII] we have also proved:

**Lemma 1.11.** 1) If $T \subseteq T_1$ are complete first order theories, $T$ is unstable as exemplified by $\varphi = \varphi(x, y)$, say $n = \ell_{g}(x) = \ell_{g}(y)$, then for some template $\Phi$ proper for the class of linear orders and nice for first order logic, $|\tau_{\phi}| = |T_1| + \aleph_{0}$ and for any linear order $I$ and $s, t \in I$ we have

$$
\text{EM}(I, \Phi) \models \varphi[\tilde{a}_s, \tilde{a}_t] \iff s < t.
$$
2) If $T \subseteq T_1$ are complete first order theories and $T$ is unsuperstable, then there are first order $\varphi_n(x, y_n) \in L(\tau_T)$ and a template $\Phi$ proper for every $I \subseteq \omega^2 \lambda$ such that for any such $I$ we have:

(a) $\eta \in \omega^2 \lambda, \nu \in \omega \lambda$ implies $EM(I, \Phi) \models \varphi_n[\bar{a}_\eta, \bar{a}_\nu] \iff \eta(n) = \nu$

(b) $EM(I, \Phi) \models T_1$ and $\Phi$ is $L(\tau_T)$-nice, $|\tau_T| = |T_1| + \aleph_0$ (note that for $\eta_1, \eta_2 \in I$ we have $\eta_1 \neq \eta_2 \Rightarrow \bar{a}_{\eta_1} \neq \bar{a}_{\eta_2}$).

3) If $T \subseteq T_1$ are complete first order theories and $\kappa = \text{cf}(\kappa) < \kappa(T)$ then

(a) there is a sequence of first order formulas $\varphi_i(x, y_i)$ (for $i < \kappa$) witnessing $\kappa < \kappa(T)$ i.e. there are a model $M$ of $T$ and sequences $\bar{a}_\eta$ for $\eta \in \omega^2 \lambda$ such that for $\eta \in \omega^2 \lambda, \nu \in \omega \lambda, i < \kappa, \alpha < \lambda$ we have $M \models \varphi_i[\bar{a}_\eta, \bar{a}_\nu (\alpha)] \iff \alpha = \eta(i)$.

(b) for any $\langle \varphi_i(x, y_i) : i < \kappa \rangle$ as in (a) there is a nice template $\Phi$ proper for $K^\kappa_{tr}$ such that for any $\lambda$:

$\alpha$) if $\eta \in \omega^2 \lambda, \nu \in \omega \lambda, i < \kappa, \alpha < \lambda$ then $GEM(\omega^2 \lambda, \Phi) \models \varphi_i[\bar{a}_\eta, \bar{a}_\nu (\alpha)] \iff \alpha = \eta(i)$;

$\beta$) $GEM(I, \Phi) \models T_1$;

$\gamma$) $\Phi$ is $L(\tau_T)$-nice;

$\delta$) $|\tau_T| = |T_1| + \aleph_0$.

Proof. See [Sh:c], Ch.VII,[3], but here we can conclude the consideration as the definition of unstable or unsuperstable and of $\kappa < \kappa(T)$, respectively (note that there we use a partition theorem and possibly replace $\varphi_i(x, y_i)$ by $\varphi_i(x, y_i') \sim_{\varphi_i(x, y_i')}\varphi_i(x, y_i''')$).

Remark 1.12. On $K^\omega_{\kappa}$ for $L_{\omega^1 + \aleph_0}$ we need the Ramsey property defined below, see [Sh:c], Ch.VIII,[2] and [Sh:c], Ch.VIII,[3], respectively.

(b20) In [Sh:c], Ch.VIII,[2] we actually proved:

Theorem 1.13. 1) If $\lambda > |\tau_T|$, and $\Phi, \tau_T, \langle \varphi_n : n < \omega \rangle$ are as in Lemma [Sh:c], Ch.VII,[2] (and $\Phi$ is almost $L(\tau_T)$-nice) then we can find $I_n \subseteq \omega^2 \lambda$ (for $\alpha < 2^\lambda$), $|I_n| = \lambda$ such that for $\alpha \neq \beta$ there is no one-to-one function from $GEM(I_n, \Phi)$ onto $GEM(I_\beta, \Phi)$ preserving the $\pm \varphi_n$ for $n < \omega$.

2) If $\lambda$ is regular, also for $\alpha \neq \beta$ there is no one-to-one function from $GEM(I_n, \Phi)$ into $GEM(I_\beta, \Phi)$ preserving the $\pm \varphi_n$ for $n < \omega$.

3) The $\varphi_n$'s do not need to be first order, just their vocabularies should be $\subseteq \tau_T$. But instead of $\Phi$ is almost $L(\tau_T)$-nice" we need just $\Phi$ is almost $\{\pm \varphi_n(\ldots, \sigma(x_\ell), \ldots)_{\ell < \ell(n)} : \alpha < \omega, \sigma \alpha \text{ terms of } \tau_T \}$-nice" and we should still demand (as in all this section)

$\ast$) the $\bar{a}_\eta$ are finite (and we are assuming that the functions are finitary).

4) So if as in Lemma [Sh:c], Ch.VII, $\varphi_n \in \mathcal{L}(\tau)$ then $\{M_\alpha | \tau : \alpha < 2^\lambda \}$ are $2^\lambda$ non-isomorphic models of $T$ of cardinality $\lambda$.

$^1$In fact $EM(I, \Phi)$ is well defined for $I \in K^\omega_{\kappa}$. 

---

[Sh:c] 10 S. SHELAH
Definition 1.15. A class $\mathcal{K}$, which is $
abla$-unstable, we use $\varphi_{n}$ as in the vocabulary $\tau$. E.g., for $T \subseteq T_{1}$ first order, $T$ unstable, we use $\varphi_{n} \in \mathbb{L}(\tau_{T})$.

1) Applying Definition 1.13, we usually look at the $\tau$-reducts of the models $GEM(I, \Phi)$ as the objects we are interested in, where the $\varphi_{n}$'s are in the vocabulary $\tau$. E.g., for $T \subseteq T_{1}$ first order, $T$ unstable, we use $\varphi_{n} \in \mathbb{L}(\tau_{T})$.

2) The case $\lambda = |\tau_{T}|$ harder. In $\text{Sh:c}$, Ch.VIII $\delta \delta$, the existence of many models in $\lambda$ is proved for $T$ unstable, $\lambda = |\tau_{T}| + 8_{1}$ and there (in some cases) “$T_{1}, T$ first order” is used.

§ 1(C). Finding Templates.

How do we find templates $\Phi$ as required in § 1.11 and parallel situations?

Quite often in model theory, partition theorems (from finite or infinite combinatorics) together with a compactness argument (or a substitute) are used to build models. Here we phrase this generally. Note that the size of the vocabulary ($\mu$ in the “($\mu, \lambda)$-large”) is a variant of the number of colours, whereas $\lambda$ is usually $\mu$; it becomes larger if our logic is complicated.

Definition 1.15. Fix a class $\mathcal{K}$ (of index models) and a logic (or logic fragment) $\mathcal{L}$.

1) An index model $I \in \mathcal{K}$ is called $(\mu, \lambda, \chi)$-Ramsey for the logic $\mathcal{L}$ when:

(a) the cardinality of $I$ is $\leq \chi$ and every qf (= quantifier free) type $p$ (in $\tau(K)$) which is realized in some $J \in \mathcal{K}$ is realized in $I$,

(b) for every vocabulary $\tau_{1}$ of cardinality $\leq \mu$, a $\tau_{1}$-model $M_{1}$ and an indexed set $\langle b_{t} : t \in I \rangle$ of finite sequences from $|M_{1}|$ with $fg(b_{t})$ determined by the quantifier free type which $t$ realizes in $I$ there is a template $\Phi$, which is proper for $K$, with $|\tau_{K}| \leq \lambda$ such that ($\tau_{1} \subseteq \tau_{K}$ and):

(*) for any $(\tau(K))$-quantifier free type $p$, $I_{1} \in \mathcal{K}$ and $s_{0}, \ldots, s_{n-1} \in I_{1}$ for which $\langle s_{0}, \ldots, s_{n-1} \rangle$ realizes $p$ in $I_{1}$ and for any formula $\varphi = \varphi(x_{0}, \ldots, x_{m-1}) \in \mathcal{L}(\tau_{1})$

and $\tau_{1}$-terms $\sigma_{\ell}(y_{0}, \ldots, y_{n-1})$ for $\ell = 0, \ldots, m-1$ we have

(**) if for every $t_{0}, \ldots, t_{n-1} \in I$ such that $\langle t_{0}, \ldots, t_{n-1} \rangle$ realizes $p$ in $I$ we have $M_{1} \vDash \varphi[\sigma_{0}(b_{t_{0}}, \ldots, b_{t_{n-1}}), \sigma_{1}(b_{t_{0}}, \ldots, b_{t_{n-1}}), \ldots, \sigma_{m-1}(b_{t_{0}}, \ldots, b_{t_{n-1}})]$

then $GEM(I_{1}, \Phi) \models \varphi[\sigma_{0}(a_{s_{0}}, \ldots, a_{s_{n-1}}), \sigma_{1}(a_{s_{0}}, \ldots, a_{s_{n-1}}), \ldots, \sigma_{m-1}(a_{s_{0}}, \ldots, a_{s_{n-1}})]$.

2) The class $K$ of index models is called explicitly $(\mu, \lambda, \chi)$-Ramsey for the logic $\mathcal{L}$ if some $I \in \mathcal{K}$ of cardinality $\leq \chi$ is $(\mu, \lambda)$-Ramsey for $\mathcal{L}$. A class $K' \subseteq K$ of index models is called $(\mu, \lambda, i, \chi)$-Ramsey (inside $K$, which is usually understood from context), when:

(a) every member of $K'$ has cardinality $\leq \chi$ and every quantifier free type $p$ in $\tau(K')$ realized in some $J \in \mathcal{K}$ is realized in some $I \in K'$,
(b) for every vocabulary \( \tau_1 \) of cardinality \( \leq \mu \) and \( \tau_1 \)-models \( M_I \) for \( I \in K' \), and \( b, t, e \in k^{1,I}(M_I) \), where \( k(I, t) < \omega \) depends just on \( tp_{qf}(t), \emptyset, I \) there is a template \( \Phi \) proper for \( K \) with \( |\tau_\Phi| \leq \lambda \) such that \( \tau_1 \subseteq \tau_\Phi \) we have \((*)\) only in \((**)\) we should also say “every \( I \in K' \)”. Let “\((\mu, \chi)\)-Ramsey” mean “\((\mu, \mu, \chi)\)-Ramsey”. Let “\(\mu\)-Ramsey” mean “\((\mu, \chi)\)-Ramsey for some \( \chi \)”.

3) In all parts of \([k_{15}, k_{16}, k_{11}] \), if \( \mathcal{L} \) is first order logic, we may omit it. If \( \chi = \mu \) we may omit \( \chi \). Similarly in other parts of \([k_{15}, k_{16}, k_{12}, k_{13}, k_{14}, k_{18}, k_{17}] \).

4) For \( f: \text{Card} \rightarrow \text{Card} \), we say \( K \) is \( f \)-Ramsey for \( \mathcal{L} \) when it is \((\mu, f(\mu))\)-Ramsey for \( \mathcal{L} \) for every (infinite) cardinal \( \mu \). We say \( K \) is Ramsey for \( \mathcal{L} \) if it is \((\mu, \mu)\)-Ramsey for \( \mathcal{L} \) for every \( \mu \).

5) We say \( K \) is \( * \)-Ramsey for \( \mathcal{L} \) if it is \( f \)-Ramsey for \( \mathcal{L} \) for some \( f: \text{Card} \rightarrow \text{Card} \).

**Definition 1.16.** Let \( K \) be a class of (index) models and \( \mathcal{L} \) a logic.

1) We say \( I \in K \) is (almost) \( \mathcal{L} \)-nicely \((\mu, \lambda, \chi)\)-Ramsey for \( K \) when \([k_{15}] \) (1) holds, but in addition \( \Phi \) is (almost) \( \mathcal{L} \)-nice. Similarly replacing \( I \) by a set \( K' \subset K \).

2) The class \( K \) is called explicitly (almost) \( \mathcal{L} \)-nicely \((\mu, \lambda, \chi)\)-Ramsey when some \( I \in K \) is (almost) \( \mathcal{L} \)-nicely \((\mu, \lambda, \chi)\)-Ramsey.

3) For \( f: \text{Card} \rightarrow \text{Card} \), we say \( K \) is (almost) \( \mathcal{L} \)-nicely \( f \)-Ramsey when \( \mathcal{L} \)-Ramsey when \( \mu \) we have: \( K \) is (almost) \( \mathcal{L} \)-nicely \((\mu, f(\mu))\)-Ramsey for every (infinite) cardinal \( \mu \). We omit \( f \) for the identity function.

4) We say \( K \) is (almost) \( \mathcal{L} \)-nicely \( * \)-Ramsey when for some \( f \), it is (almost) \( \mathcal{L} \)-nicely \( f \)-Ramsey.

**Definition 1.17.** In \([k_{15}, k_{16}] \) we add “strongly” when we strengthen \([k_{15}] \) (1) by asking in \((*)\) that for any \( \tau(K) \)-quantifier free type \( p \) and \( s_0, \ldots, s_{n-1} \in I_1 \) such that \((s_0, \ldots, s_{n-1}) \) realizes \( p \) in \( I_1 \) we can find some \( t_0, \ldots, t_{n-1} \) suitable for all \( \varphi, s_0, \ldots \) simultaneously (this helps for omitting types).
Theorem 1.19. \( K^c_{tr} \) is the nicely \( * \)-Ramsey for \( L_{\lambda^+,\kappa_0} \) if for example there are arbitrarily large measurable cardinals (in fact, large enough cardinals consistent with the axiom \( V = L \) suffice).

We shall not repeat the proof.

Lemma 1.20. Suppose \( K_1, K_2, K_3 \) are classes of models, \( \Psi \) is a proper template for \( (K_1, K_2) \), \( \Psi \) proper template for \( (K_2, K_3) \) then there is a unique template \( \Theta \) that is proper for \( (K_1, K_3) \) and for \( I \in K_1 \)
\[
\text{GEM}(I, \Theta) = \text{GEM}(\text{GEM}_{\tau(K_2)}(I, \Phi), \Psi))
\]

In this case we may write \( \Theta \) as \( \Psi \circ \Phi \).

Proof. Straightforward. \( \blacksquare \)

Lemma 1.21. Suppose \( K \) is a class of index models, \( \tau = \tau(K) \) and
\( (*) \) there is a template \( \Psi \) proper for \( K \) such that \( \tau_K \subseteq \tau_\Psi \), \( |\tau_\Psi| = |\tau_K| + \aleph_0 \) and for \( I \in K \) if \( \text{GEM}_{\tau(K)}(I, \Psi) \) is strongly \( (\aleph_0, \text{qf}) \)-homogeneous over \( I \), i.e., if \( I = \{t_1, \ldots, t_n\}, s = \{s_1, \ldots, s_n\} \) realize the same quantifier free type in \( I \), then some automorphism of \( J \) takes \( \bar{a}_t \) to \( \bar{a}_s \).

We conclude that: if \( K \) is \( (\mu, \lambda, \chi) \)-Ramsey for \( \mathcal{L} \) and \( |\tau_\Psi| \leq \mu \) then \( K \) is almost \( \mathcal{L} \)-nicely \( (\mu, \lambda, \chi) \)-Ramsey for \( \mathcal{L} \).

Proof. Just chase the definitions. \( \blacksquare \)

Remark 1.22. 1) E.g. for \( \mathcal{L} \subseteq L_{\lambda_1, \kappa_0} \) we get in \( \mathcal{L} \)-nice even \( \mathcal{L} \)-nice.
2) The assumption \( (*) \) of 1.21(1) holds for \( K_{or}, K_{tr}^c, K_{tr}^c \) (as well as the other \( K \)'s from \([\text{Sh:331}]\)).

Conclusion 1.23. Assume that
\( a) \) \( K_{or} \) is \( (\mu, \lambda) \)-Ramsey for \( \mathcal{L} \),
\( b) \) \( T \) is an \( \mathcal{L} \)-theory (in the vocabulary \( \tau(T) \)), \( |\tau(T)| \leq \mu \),
\( c) \) \( \varphi_\ell(R_\ell, \bar{x}, \bar{y}) \in \mathcal{L}(\tau(T) \cup \{R_\ell\}) \) for \( \ell = 1, 2 \) (and \( R_\ell \) is disjoint from \( \tau(T) \) and \( R_{3-\ell} \), and \( T \cup \{\varphi_1(R_1, \bar{x}, \bar{y}), \varphi_2(R_2, \bar{x}, \bar{y})\} \) has no model,
\( d) \) for every \( I \in K_{or} \) there is a model \( M_I \) of \( T \), and \( \bar{a}_t \in \langle R \rangle M_{t \in I} \) such that:
\[
t < s \Rightarrow M \models (\exists R_1)\varphi_1(R_1, \bar{a}_s, \bar{a}_s)
\]
\( s \leq t \Rightarrow M \models (\exists R_2)\varphi_2(R_2, \bar{a}_s, \bar{a}_t) \).

Then for \( \lambda \geq \mu + \aleph_1, \hat{1}(\lambda, T) = 2^\lambda \) and if \( \tau \subseteq \tau_T \) and \( \varphi_\ell \subseteq \mathcal{L}(\tau \cup R_\ell) \) for \( \ell = 1, 2 \) then \( \hat{1}_\tau(\lambda, \tau) = 2^\lambda \).

Proof. Obvious by now (e.g. use \( \text{Sh:238}(3) \) and \( \text{Sh:23}(3) \) below). \( \blacksquare \)

Conclusion 1.24. The parallel of 1.23 for \( K_{tr}^c \) instead \( K_{or} \) holds if \( \lambda > \mu \).
Claim 1.26. Assume that

(a) $K$ is a definition of a class of models with vocabulary $\tau$ (the “index models’’); where $\tau$ and the parameters in the definition belongs to $\mathcal{H}(\chi^+)$,
(b) $\mathcal{L}$ is a definition of a logic or logic fragment, the parameters of the definition belong to $\mathcal{H}(\chi^+)$ and $\lambda \geq \chi$,
(c) in the definition of “$\Phi$ is (almost) $\mathcal{L}$-nice” for $\Phi$ proper for $K$ with $|\tau_\Phi| < \chi$ (see §1.20), $\lambda$; so without loss of generality $\Phi \in \mathcal{H}(\chi)$ it suffices to restrict ourselves to $I$ of cardinality $< \chi$,
(d) $\mathbb{P}$ is a forcing notion not adding subsets to $\lambda$, and preserving clauses (a), (b) and (c) (i.e., the definitions of $K$ and $\mathcal{L}$ have these properties) and no new quantifier free complete $n$-types are realized in $I \in K$,
(e) in $V^\mathbb{P}$, there is a member $I^*$ of $K$, which is $(\chi, \lambda)$-Ramsey for $\mathcal{L}$ (or an almost $\mathcal{L}$-nicely $(\chi, \lambda)$-large) for an $\mathcal{L}$-nicely $(\chi, \lambda)$-Ramsey$^*$ or such a subset $K'$ of $K$. For $I \in K$ let $P^n_I = \{ p : p$ is complete quantifier-free $\tau_{\mathcal{L}}^n$-type realized in $I \}$.

Then, we can conclude that there is a $\Phi$ such that:

(N) $\Phi$ is an (almost) $\mathcal{L}$-nice template $\Phi$, proper for $K$. 

Proof. By §1.23 (or use §1.31).
Claim 1.27. Assume that

(a) \( K \) is a class of (index) models,
(b) \( \kappa \) is a cardinal, for \( \alpha < (2^\kappa)^+ \) the structure \( I_\alpha \in K \) realizes all quantifier free \( \tau_K \)-types (in \( < \omega \) variables) realized in some \( I \in K \), and their number is \( \leq \kappa \),
(c) if \( n < \omega, \alpha < \beta < (2^\alpha)^+, \eta \) is a model, \( \tau(\eta) \leq \kappa, \alpha^*_\eta < \kappa^+ \) for a complete quantifier free \( \tau_K \)-1-type \( \tau \) realized in \( I_\beta, b_\tau \in \eta^{\alpha^*_\eta}, N \), then we can find \( I'_\alpha \subseteq I_\beta \) isomorphic to \( I_\alpha \) such that
  
  \( \ast \) if \( \bar{s}, \bar{t} \in m(I'_\alpha), m \leq n \) and they realize the same quantifier free type in \( I'_\alpha \), then \( \bar{b}_\ell = (b_\ell : \ell < m) \) and \( \bar{b}_s = (b_\ell : \ell < m) \) realizes the same quantifiers free type in \( N \),
(d) \( \tau \) is a vocabulary, \( |\tau| \leq \kappa, \psi \in \ell_{\kappa^+, \kappa_0}(\tau) \) and \( \alpha^*_\psi < \kappa^+ \) for \( p \) a complete quantifier free \( \tau_K \)-1-type realized in every \( I_\alpha, \mathcal{L} \subseteq \ell_{\kappa^+, \kappa_0}(\tau) \) is a fragment of cardinality \( \kappa \) to which \( \psi \) belongs,
(e) for every \( \alpha < (2^\alpha)^+ \), there is a model \( N_\alpha \) of \( \psi \) with \( \bar{b}_\alpha \in \eta^*_\alpha(N_\alpha) \) for \( t \in I_\alpha \), where \( \alpha^*_\psi = \alpha^*_\psi(t, \emptyset, I_\alpha) \).

Then there is a \( \mathcal{L} \)-nice template \( \Phi \), such that:

\( \forall \) for \( I \in K, m < \omega \) and \( \bar{t} \in mI \) we have: the \( \mathcal{L} \)-type which is \( \bar{a}_\bar{t} \)-realized in \( \text{GEM}(I, \Phi) \) is realized in some \( N_\alpha \) by some \( \bar{b}_\bar{t} \), where \( tp_{\eta}(\emptyset, I_\alpha) = tp_{\eta}(\bar{t}, \emptyset, I) \).

In other words, \( I_\alpha : \alpha < (2^\kappa)^+ \) is \( \kappa \)-Ramsey for \( \mathcal{L} \).

Proof. We can expand \( N_\alpha \) by giving names to all formulas in \( \mathcal{L} \) and adding Skolem functions (to all first order formulas in the new vocabulary), so we have a \( \tau^+ \)-model \( N^*_\alpha, \tau^+ \supseteq \exists \tau = \tau(\bar{\psi}), |\tau^+| \leq \kappa \) correspondingly we extend \( \mathcal{L} \) to a fragment \( \mathcal{L}^+ \) of \( \ell_{\kappa^+, \kappa_0}(\tau^+) \) of cardinality \( \kappa \).

By induction on \( n < \omega \) we choose \( A_n, f_n, \langle I^n_\alpha : \alpha \in A_n \rangle \) such that:

(1) \( A_n \) is an unbounded subset of \( (2^\kappa)^+ \),
(2) \( f_n \) is an increasing function from \( (2^\kappa)^+ \) onto \( A_n \) such that \( \alpha < f_n(\alpha) \),
(3) \( I^n_\alpha \) is a submodel of \( I^I_\alpha \) isomorphic to \( I^I_{f^-1(\alpha)} \),
(4) if \( n > m > 0, \alpha_1, \alpha_2 < (2^\alpha)^+, \bar{t}_1 \in m(I^n_{f_\alpha(\alpha_1)}), \bar{t}_2 \in m(I^n_{f_\alpha(\alpha_2)}), tp_{\eta}(\bar{t}_2, \emptyset, I_{f_\alpha(\alpha_2)}) = tp_{\eta}(\bar{t}_1, \emptyset, I_{f_\alpha(\alpha_1)}) \), then the quantifier free type of \( \bar{b}_\bar{t}_1 \) in \( N_{f_\alpha(\alpha_1)} \) is equal to the quantifier free type of \( \bar{b}_\bar{t}_2 \) in \( N_{f_\alpha(\alpha_2)} \),
(5) \( A_{n+1} \subseteq A_n \) and \( \alpha \in A_{n+1} \Rightarrow I^n_{\kappa^{+1}} \subseteq I^{n+1}_\alpha \).

For \( n = 0 \) let \( A_0 = (2^\kappa)^+ \) and \( I^0_\alpha = I_\alpha \).

For \( n + 1 \), for each \( \alpha \) we apply assumption (c) to \( N_{f_\alpha(\alpha+n+1)} \), \( I^{n+1}_{f_\alpha(\alpha+n+1)} \), \( \langle \bar{b}_{\bar{t}_t} : t \in I^n_{f_\alpha(\alpha+n+1)} \rangle \), getting \( I^{n+1}_{f_\alpha(\alpha+n+1)} \). We define an equivalence relation

\( \Phi \in \mathcal{H}(\lambda^+) \) hence also \( \tau_\Phi \in \mathcal{H}(\lambda^+) \)
Conclusion 1.28. Assume that

(a) \( \mathcal{L} \) a fragment of \( L_{\omega_1, \omega} \), \( T \) is theory in \( \mathcal{L}(\tau) \), and \( \theta \geq \kappa + |T| + |\tau| + |\mathcal{L}| \).
(b) \( \varphi_\alpha = \varphi_\alpha(x_0, \ldots, x_{\kappa_\alpha - 1}) \in \mathcal{L}(\tau) \) for \( \alpha < \alpha(*) \) (where \( \alpha(*) < \kappa^+ \) may be finite),
(c) for some \( \mu > \theta \), in any forcing extension of \( V \) by a \( \mu \)-complete forcing notion the following holds for any \( \lambda \):
   if \( R_\alpha \) is a subset of \( |\lambda|^{\kappa_\alpha} \) for \( \alpha < \alpha(*) \) then for some model \( M \) of \( T \) and \( a_\alpha \in M \) for \( \alpha < \lambda \) we have: if \( \alpha < \alpha(*) \), \( \gamma_0 < \ldots < \gamma_{\kappa_\alpha - 1} < \lambda \), then \( M \models \varphi_\alpha([a_0, \ldots, a_{\kappa_\alpha - 1}]) \subseteq \mathcal{P}(\{0, \ldots, \gamma_{\kappa_\alpha - 1}\}) \in R_\alpha \)
(d) Let \( K \) be the class of \( (I, <, R_0, \ldots, R_{\alpha < \alpha(*)}, I, <) \) linear order, \( R_\alpha \) a symmetric irreflexive \( k_\alpha \)-place relation on \( I_\alpha \).

Then we can find a complete \( T_1 \supseteq T \) with Skolem functions, and a template \( \Psi \) proper for \( K \) and nice, such that:

(a) \( \tau \subseteq \tau_\Psi \) (even \( \tau_\Psi \) extends \( \tau \)), and \( |\tau_\Psi| \leq \theta \) and \( |T_1| \leq \theta \),
(b) \( \Psi \) is nice for \( \mathcal{L} \) and \( GEM(I, \Psi) \models T_1 \) for \( I \in K \),
(c) if \( \alpha < \alpha(*) \), and \( I \models t_0 < \ldots < t_{\kappa_\alpha - 1} \) then:
   \[ GEM(I, \Psi) \models \varphi_\alpha(a_0, \ldots, a_{\kappa_\alpha - 1}) \text{ iff } I \models R_\alpha(t_0, \ldots, t_{\kappa_\alpha - 1}) \].

Proof. We would like to apply 1.27, e.g., with \( I_\alpha \in K \) being of cardinality \( \beth_\omega(\alpha) \), and being \( \beth_\omega(\alpha)^+ \)-saturated for quantifier free types in the natural sense (such \( N_\alpha \) exists by the compactness theorem). However why does assumption (c) of 1.27 hold? By [Sh:289] there is a \( \theta^+ \)-complete forcing notion \( \mathbb{P} \) such that in \( V^\mathbb{P} \) this will hold; it would not make a real difference if we replace \( \beth_{\omega_1}(\alpha) \) by other suitable cardinal. But by 1.26 this suffices (as our assumptions are absolute enough).

Remark 1.29. For first order \( T \), this help in Laskowski-Shelah [LwSh:687].

The next conclusion fulfills our promise that for \( T \) with the OTOP (omitting type order property) we can in ZFC prove that existence of suitable templates, inspite of the formula exemplifying the order property not being first order.
Conclusion 1.30. If $T$ is first order countable with the OTOP (see [Sh:c, Ch.XII], the omitting type order property) then for some sequence $\phi = \langle \phi_i(x, \bar{y}, \bar{z}) : i < i(*) \rangle$ of first order formulas in $L(\tau_T)$ and template $\Phi$ proper for linear orders we have:

\begin{enumerate}
\item[(a)] $\tau_T \subseteq \tau_\Phi$, $|\tau_\Phi| = |\tau_T| + \aleph_0$,
\item[(b)] $\text{GEM}_{\tau(T)}(I, \Phi) \models T$ for $I \in K_{\text{org}}$,
\item[(c)] if $I \in K_{\text{org}}$ and $s, t \in I$ then
\end{enumerate}

$$\text{GEM}_{\tau(T)}(I, \Phi) \models (\exists \bar{x}) \bigwedge_{i < i(*)} \phi_i(x, \bar{a}_s, \bar{a}_t) \text{ iff } I \models sRt.$$  

Proof. Similarly to the previous conclusion: OTOP is defined in [Sh:c, Ch.XII, 4.1, p.608], in a way giving clause (e) of d17 above directly, but we need to know that it is absolute (or just preserved by $\lambda$-complete forcing), which holds by [Sh:c, Ch.XII,4.3,p.609]. □

For “a $T$ is a stable first order $T$ with DOP” this is less interesting as the main case is for $\kappa$-saturated models of $T$, not for pseudo elementary classes. In this case, we can prove the result in ZFC directly, see more in the beginning of §2A.

Now Claim d17 apply to the class of linear orders, so a natural question is to find a parallel also for the class $K_{\omega}$, which is the aim of the next claim, see more in Grossberg-Shelah [GrSh:238] and more lately in [Sh:F1809].

It is still conceivable that there are suitable partition relations which are enough, see discussion in [Sh:F189]. Anyhow what we have is:

Conclusion 1.31. Claim d17 applies to the class of trees with $\omega$ levels.

Proof. By the proof in [Sh:c, Ch.VII, §3], i.e., looking at what we use and applying the Erdős-Rado theorem. □

Discussion 1.32. We may consider and get similar results for the following:

\begin{enumerate}
\item[(*)$_1$] we say $f$ is a ($\bar{\varphi}_1, \bar{\varphi}_2$)-homomorphism from $M_1$ into $M_2$ when:
\begin{enumerate}
\item[(a)] $M_1, M_2$ are models, not necessarily of the same vocabulary
\item[(b)] $f$ is a function from $M_1$ into $M_2$
\item[(c)] $\bar{\varphi}_\ell = \langle \varphi^\ell_i(x_{n_i}) : i < i_\ell \rangle$ for $\ell = 1, 2$ where $\varphi^\ell_i$ is a formula in the vocabulary $\tau(M_\ell)$
\item[(d)] if $i < i_\ell$ and $a_n \in M_2$ for $n < n_*$ and $M_1 \models \varphi^\ell_i[a_n, \ldots]_{n < n_*}$, then $M_2 \models \varphi^\ell_i[a_n, \ldots]_{n < n_*}$
\end{enumerate}
\item[(*)$_2$] above we replace “homomorphism” by “embedding” when $f$ is one to one; and in clause (d) we replace implication by equivalence.
\end{enumerate}

Note that (*)$_2$ is a special case of (*)$_1$, i.e. restricting ourselves in (*)$_1$ to the case:

\begin{enumerate}
\item[(a)] for every $i < i_\ell$ for some $j < \ell_\ast, \varphi^\ell_j$ is equivalent to $\neg \varphi^\ell_i$
\item[(b)] $(\exists i < i_\ast)(n_i = 2$ and $\varphi^\ell_i = (x_0 \neq x_1))$.
\end{enumerate}
§ 2. Models Represented in Free Algebras and Applications

This section presents a framework, which tries to separate the model theory and combinatorics of $\mathfrak{Sh}:c$ and improve it. We shall prove the combinatorics in $\mathfrak{Sh}:c$, §(2E) and more in $\mathfrak{Sh}:309$ and $\mathfrak{Sh}:331$; here we do basic combinatorics and we try to show how to apply it. More applications and more combinatorics are in $\mathfrak{Sh}:511$.

We sometimes need $\tau_\Phi$ with function symbols with infinitely many places and deal with logics $L$ with formulas with infinitely many variables. The example in §(1D) illustrates why.

§ 2(A). Representation, non-embeddability and bigness.

We also sometimes would like to rely on a well ordered construction, i.e., on the universe of $\mathfrak{M}_{\mu,\kappa}$ (see Definition 2.1 below) there is a well ordering which is involved in the definition of indiscernibility (see $\mathfrak{Sh}:c$). This means that we have in addition an arbitrary well-order relation. E.g., we would like to build many non-isomorphic $\aleph_1$-saturated models for a stable not superstable first order theory, with the DOP (dimensional order property, see $\mathfrak{Sh}:c$, Ch.X) so for some $\varphi(\bar{x},\bar{y})$ (not first order), for any cardinal $\lambda$ for some model $M$ of $T$, we have a family $\{\bar{a}_\alpha : \alpha < \lambda \}$ of sequences of length $\leq |T|$ in $M$ with $M \models \varphi[\bar{a}_s,\bar{a}_t]$ iff $\alpha < \beta$. The formula $\varphi$ says: there are $z_\alpha (\alpha < |T|^+)$ such that $x^y \langle z_\alpha : \alpha < |T|^+ \rangle$ realizes a type $p$. So there is a template $\Phi$ proper for $K_{\text{or}}$ such that for $I \in K_{\text{or}}$ and $s, t \in I$ we have

$$\text{EM}_{\tau(T)}(I, \Phi) \models \varphi[\bar{a}_s,\bar{a}_t] \text{ iff } I \models s < t$$

($< \text{ a relevant order}$), but we need to make them $\aleph_1$-saturated. Ultrapowers may well destroy the order. The natural thing is to make $M_I$ $\aleph_1$-constructible over $\text{GEM}_{\tau(T)}(I, \Phi)$, that is its set of elements is $\{b_\alpha : \alpha < \alpha \}$, $b_\alpha$ realizing over $\text{EM}_{\tau(T)}(I, \Phi) \cup \{b_\beta : \beta < \alpha \}$ in $M_I$ a complete type which is $\aleph_1$-isolated. So not only are the $\bar{a}_t$ infinite and the construction involves infinitary functions, but $a \text{ priori}$ the quite arbitrary order of the constructions may play a role.

With some work we can eliminate the well order of the construction for this example (using symmetry, the non-forking calculus, see $\mathfrak{CoSh}:919$) but there is no guarantee generally and certainly it is not convenient, for example see the constructions in $\mathfrak{Sh}:136$, §3. Moreover, generally it is better to delete the requirement that the universe of the model is so well defined.

This motivates the following definition.

Definition 2.1.

(a) $\tau(\mu, \kappa) = \tau_{\mu,\kappa}$ is the vocabulary with function symbols

$$\{F_{i,j} : i < \mu, j < \kappa \},$$

where $F_{i,j}$ is a $j$-place function symbol and $\kappa$ is a regular cardinal

(b) $\mathfrak{M}_{\mu,\kappa}(I)$ is the free $\tau$-algebra generated by $I$ for $\tau = \tau_{\mu,\kappa}$

(c) we may write $\mathfrak{M}_\mu(I)$ when $\kappa = \aleph_0$ and $\mathfrak{M}(I)$ when $\mu = \aleph_0 = \kappa$.

We use the following notation in the remainder of this definition:
• Let \( f : M \rightarrow \mathcal{M}_{\mu,\kappa}(I) \). For \( \bar{a} = \langle a_i : i < \alpha \rangle \in {^\omega}M \) let for \( i < \alpha \), \( f(a_i) = \sigma_i(\bar{t}_i) \), where \( \bar{t}_i \) is a sequence of length \( \kappa \) from \( I \) and \( \sigma_i \) is a term from \( \tau_{\mu,\kappa} \).

• Now if \( \alpha < \kappa \) then there is one sequence \( \bar{t} \) of members of \( I \) of length \( \kappa \) such that

\[
\bigwedge_i \text{Rang}(\bar{t}_i) \subseteq \text{Rang}(\bar{t});
\]

so we can find terms \( \sigma'_i \) satisfying \( f(a_i) = \sigma'_i(\bar{t}) \), so without loss of generality \( \bar{t}_i = \bar{t} \), we let \( \bar{\sigma} = \{ \sigma_i : i < \alpha \} \) and \( \bar{\sigma}(\bar{t}) \) be \( \langle \sigma_i(\bar{t}) : i < \alpha \rangle \), so \( f(\bar{a}) = \bar{\sigma}(\bar{t}) \).

Now (c) we say that \( M \) is \( \Delta \)-represented in \( \mathcal{M}_{\mu,\kappa}(I) \) when there is a function \( f : M \rightarrow \mathcal{M}_{\mu,\kappa}(I) \) which is a \( \Delta \)-representation of \( M \) where this means: the \( \Delta \)-type of \( \bar{a} \in {^\omega}M \) (i.e., \( \text{tp}_\Delta(\bar{a},\emptyset,M) \)) can be calculated from the sequence of terms \( \langle \sigma_i : i < \alpha \rangle \) and \( \text{tp}_{\emptyset}(\langle \bar{t}_i : i < \alpha \rangle,\emptyset,I) \) where \( f(\bar{a}) = \langle \sigma_i(\bar{t}_i) : i < \alpha \rangle \) (from (b), so if \( f(\bar{a}) = \bar{\sigma}(\bar{t}) \) from then can be calculated \( \bar{\sigma} \) and \( \text{tp}_{\emptyset}(\bar{t},\emptyset,I) \)).

We may say “\( M \) is \( \Delta \)-represented in \( \mathcal{M}_{\mu,\kappa}(I) \) by \( f \)” similarly below.

(d) We say that \( M \) is weakly \( \Delta \)-represented in \( \mathcal{M}_{\mu,\kappa}(I) \) when some function \( f : M \rightarrow \mathcal{M}_{\mu,\kappa}(I) \) is a weak \( \Delta \)-representation of \( M \) in \( \mathcal{M}_{\mu,\kappa}(I) \) which means:

there is a well-ordering \( < \) of the universe of \( \mathcal{M}_{\mu,\kappa}(I) \) such that for \( \bar{a} \in {^\omega}M \) the \( \Delta \)-type of \( \bar{a} \) can be computed from the information described in (c) and the order \( < \) restricted to the family of subterms of the terms \( \langle \sigma_i(\bar{t}_i) : i < \alpha \rangle \).

[We introduce weak representability to deal with the dependence on the order of a construction, (cf. the discussion after [14])].

(e) (\( \alpha \)) We say \( \bar{a}_1 \sim \bar{a}_2 \mod \mathcal{M}_{\mu,\kappa}(I) \) and may say \( \bar{a}_1, \bar{a}_2 \) are similar in \( \mathcal{M}_{\mu,\kappa}(J) \) when for \( i = 1,2 \) we have \( \bar{a}_i = \langle \sigma^i_j(\bar{t}^i_j) : j < \alpha \rangle \), \( \sigma^1_j = \sigma^2_j \) and \( \text{tp}_{\emptyset}(\langle \bar{t}^i_j : j < \alpha \rangle,\emptyset,I) = \text{tp}_{\emptyset}(\langle \bar{t}^i_j : j < \alpha \rangle,\emptyset,I) \).

(\( \beta \)) for the case of weak representability we write \( \bar{a}_1 \sim \bar{a}_2 \mod \mathcal{M}_{\mu,\kappa}(I) \) and may say \( \bar{a}_1, \bar{a}_2 \) are similar in \( \mathcal{M}_{\mu,\kappa}(J) \) when in addition the mapping

\[
\{ \langle \sigma(\bar{t}^1_j),\sigma(\bar{t}^2_j) \rangle : i < \alpha, \sigma \text{ is a subterm of } \sigma^1_j = \sigma^2_j \}
\]

is a \( < \)-isomorphism (and both sides are linear orders). We write \( \bar{a}_1 \sim_A \bar{a}_2 \mod \mathcal{M}_{\mu,\kappa}(I) \) if \( \bar{a}_1 \sim \bar{a}_2 \mod \mathcal{M}_{\mu,\kappa}(I) \) whenever \( \bar{b} \in {^\omega}A \) where \( A \subseteq \mathcal{M}_{\mu,\kappa}(I) \). (This latter is especially important when we work over a set of parameters). We might, for instance, insist that \( \bar{t}^1_i \) and \( \bar{t}^2_i \) realize the same Dedekind cut over \( I_0 \subseteq I \). (So “\( M \) is \( \Delta \)-represented in \( \mathcal{M}_{\mu,\kappa}(I) \)” means: \( f(\bar{a}_1) \) similar to \( f(\bar{a}_2) \) mod \( \mathcal{M}_{\mu,\kappa} \) implies \( \bar{a}_1 \) and \( \bar{a}_2 \) realize the same \( \Delta \)-type in \( M \).)

(f) (\( \alpha \)) We say the representation is full when:

\[ c_1 \sim c_2 \mod \mathcal{M}_{\mu,\kappa}(I) \] implies \( [c_1 \in \text{Rang}(f) \Leftrightarrow c_2 \in \text{Rang}(f)] \).

(\( \beta \)) We say the weak representation is full when we replace \( \mathcal{M}_{\mu,\kappa}(I) \) by \( (\mathcal{M}_{\mu,\kappa}(I),<) \), where \( < \) is a given well ordering from clause (d).

(g) If \( \Delta \) is the family of quantifier free formulas it may be omitted.
(h) For $f : M \rightarrow \mathcal{M}_{\mu,\kappa}(I)$, let $\bar{a} \sim \bar{b} \mod (f, \mathcal{M}_{\mu,\kappa}(I))$ means
\[ f(\bar{a}) \sim f(\bar{b}) \mod \mathcal{M}_{\mu,\kappa}(I). \]
Similarly, $\bar{a} \sim \bar{b} \mod (f, \mathcal{M}_{\mu,\kappa}(I), <) \mod (\mathcal{M}_{\mu,\kappa}(I), <)$.

2) We may restrict ourselves to well orderings $< \mathcal{M}_{\mu,\kappa}(I)$ which respect subterms; this means that if $\sigma_1(t_1)$ is a subterm of $\sigma_2(t_2)$ then $\sigma_1(t_1) \leq \sigma_2(t_2)$.

Now we define a very strong negation (when $\varphi$ is “right”) to even weak representability.

**Definition 2.2.** 1) For index models $I, J$ we say $I$ is strongly $\varphi(\bar{x}, \bar{y})$-unembeddable for $\tau(\mu, \kappa)$ into $J$ when for every $f : I \rightarrow \mathcal{M}_{\mu,\kappa}(J)$ and well ordering $< \mathcal{M}_{\mu,\kappa}(I)$ there are sequences $\bar{x}, \bar{y}$ of members of $I$ such that $I \models \varphi(\bar{x}, \bar{y})$ and $\bar{x}, \bar{y}$ have “similar” $(P(\bar{I}(e)))$ images in $(\mathcal{M}_{\mu,\kappa}(J), <)$. If we delete the well ordering, we get only “$I$ is $\varphi(\bar{x}, \bar{y})$-unembeddable” If $\varphi$ clear from the context we may omit it. Note that the formula $\varphi(\bar{x}, \bar{y})$ should be in the vocabulary $\tau_I$; here almost always we have $\tau_I = \tau_I$ but this is not really necessary.

2) $K$ has the [strong] $(\chi, \lambda, \mu, \kappa)$-bigness property for $\varphi(\bar{x}, \bar{y})$ when there are $I_\alpha \in K_\lambda$ for $\alpha < \chi$ such that for $\alpha \neq \beta$ we have $I_\alpha$ is [strongly] $\varphi(\bar{x}, \bar{y})$-unembeddable for $\tau(\mu, \kappa)$ into $I_\beta$.

3) $K$ has the full [strong] $(\chi, \lambda, \mu, \kappa)$-bigness property for $\varphi(\bar{x}, \bar{y})$ when there are $I_\alpha \in K_\lambda$ for $\alpha < \chi$ such that, for $\alpha < \chi$, $I_\alpha$ is [strongly] $\varphi(\bar{x}, \bar{y})$-unembeddable for $\tau(\mu, \kappa)$ into $\bigcup_{\beta \in \chi, \beta \neq \alpha} I_\beta$ (where $\sum_{\beta \in \chi} I_\beta$ when all the $I_\beta$ are $\tau$-models for some fixed vocabulary $\tau$, is a $\tau$-model $I$ with universe the disjoint union $\bigcup_{\beta \in \chi} I_\beta$); if those universes are not pairwise disjoint we use $\bigcup_{\beta \in \chi} (\{\beta\} \times I_\beta)$; for a predicate $P \in \tau, P^I = \bigcup_{\beta \in \chi} P^{I_\beta}$, for every function symbol $F \in \tau, F^I$ is the (partial) function $\bigcup_{\beta \in \chi} F^{I_\beta}$.

4) Saying “$I$ is [strongly] $\varphi(\bar{x}, \bar{y})$-unembeddable into $J$ for function $f$ satisfying Pr” means we restrict ourselves (in $\mathbb{F}_\mathbb{F}(2)$) to function $f$ from $I$ to $\mathcal{M}_{\mu,\kappa}(J)$ satisfying Pr.

5) The most popular restriction is “$f$ finitary on some $P^I$” which means that for every $\eta \in P^I$ for some $n < \omega$, $\tau_{\mu,\kappa}$-term $\sigma$ and $\eta_0, \ldots, \eta_{n-1} \in J$ we have $f(\eta) = \sigma(\eta_0, \ldots, \eta_{n-1})$. We say $f$ is strongly finitary if in addition $\sigma$ has only finitely many subterms.

6) Clearly (4) induces parallel variants of $\mathbb{F}_\mathbb{F}(2)$, $\mathbb{F}_\mathbb{F}(3)$.

**Remark 2.3.** 1) This definition is used in proving that the model constructed from $I$ is not isomorphic to (or not embeddable into) the model constructed from $J$.

2) We may in $\mathbb{F}_\mathbb{F}(2)$ and the other variants, add: moreover, given $A \subseteq J$ of cardinality $< \kappa$ we demand that $\bar{x}, \bar{y}$ are similar over $A$. This does not make a real difference so far.

3) About the connection to $\hat{I}E(\lambda, T_1, T)$ see $\mathbb{S}$ 331]. Clearly “representable in $\mathcal{M}(I)$” is intended to be weaker relative of being a GEM$_I(I, \Phi)$-model; the next claim shows that this is the case indeed.
Claim 2.4. 1) If $\Phi$ is proper for the index model $I$ and $\mu = |\tau_\Phi|$ then GEM($I, \Phi$) can be qf-represented in $\mathcal{M}_{\mu, \emptyset}(I)$.

2) If $\Phi$ is weakly $\mathcal{L}$-nice, then we can reduce "qf" by $\mathcal{L}$.

3) We can add in parts (1) and (2) that the representation is full when $I$ is a linear order which has neither first element nor last element.

Proof. Easy, but we elaborate.

1) Let $(M, \bar{a})$ be GEM($I, \Phi$), $\bar{a} = \langle \bar{a}_s : s \in I \rangle$ for transparency assume $\ell g(\bar{a}_s) = 1$ for $s \in I$; otherwise use suitable unary functions.

For each $n < \omega$ let $(\sigma_{n, i}(x_{[n]})) : i < i_n$ list the $\tau_\Phi$-term with sets of free variables included in $x_{[n]}$; as $\mu \geq |\tau_\Phi|$ and $\mu$ is infinite, without loss of generality $i_n \leq \mu$.

Now we define a function $f$ with domain $M$ as follows:

\[(*) \text{ if } a \in M \text{ and } M \models \"a = \sigma_{n, i}(\ldots, s_{\ell}, \ldots)_{\ell < n}\" \text{ and } s_0 < I \ldots < I s_{n-1}, \text{ then } f(a) = F_{n, i}(\ldots, s_{\ell}, \ldots)_{\ell < n} \text{ for some } n < \omega, i < i_n.\]

The choice is not unique but each $f(a)$ is defined in at least one way; so choose one of the values; it is easy to check that $f$ is as required, but this is not so nice way to define $f$, so we give a better proof.

For transparency assume we choose $\langle \sigma_{n, i}(x_{[n]}) : i < i_n, n < \omega \rangle$ as above. For each such pair $(n, i)$ let $u = u(n, i)$ be a subset of $n$ of minimal cardinality such that:

\[(*)^1_{n, i} \text{ if } s_0 < I \ldots < I s_{n-1} \text{ and } t_0 < I \ldots < I t_{n-1} \text{ then } (\forall i \in u)(s_i = t_i) \Rightarrow \sigma_{n, i}^M(s_0, \ldots, s_{n-1}) = \sigma_{n, i}^M(t_0, \ldots, t_{n-1}).\]

Easily:

\[(*)^2_{n, i} u = u(n, i) \text{ is unique.}\]

[Why? As $I$ is infinite (really less is necessary).]

Next

\[(*)^3 \text{ for } a \in M \]

\[(a) n = n_a \text{ is the minimal } n \text{ such that } a \in \{ \sigma_{n, i}^M(\ldots, a_{s}, \ldots)_{s < n} : i < i_n \text{ and } s_0 < I s_1 < I \ldots < I s_{n-1} \text{ are from } I \}\]

\[(b) \text{ fixing } n = n_a, i = i_a \text{ is the minimal } i \text{ such that } a \in \{ \sigma_{n, i}^M(\ldots, a_{s}, \ldots)_{s < n} : s_0 < I s_1 < I \ldots < I s_{n-1} \}\]

\[(c) \text{ choose } \langle a_{s_a, \ell} : \ell < n \rangle \text{ such that } a = \sigma_{n, i}^M(a_{s_0, 0}, \ldots, a_{s_{n-1}}) \text{ and } a_{s_0, 0} < I \ldots a_{s_{n-1}} \]

\[(d) \text{ let } u_a = u(n_a, i_a) \text{ and } m_a = m_{n, i} = |u_a|\]

\[(e) \text{ for } n < \omega, i < i_n \text{ let } h_{n, i} \text{ be the unique increasing function from } m_{n, i} \text{ onto } u_{n, i}.\]

Lastly, we define a function $f$ with domain $M$

\[(*)^4 \text{ for } a \in M \text{ we let } f(a) = F_{m, i}(\ldots, s_{h_{i}(\ell)}, \ldots)_{\ell < m} \text{ when:}\]

\[\bullet_1 n = n_a, i = i_a, s_0 < I \ldots < I s_{n-1}, h = h_a\]

\[\bullet_2 a = \sigma_{n, i}^M(a_{s_0}, \ldots, a_{s_{n-1}}).\]
Remark 2.5. We can omit the extra assumption on $I$ in Example 2.6, if we add the following reasonable assumption:

- if $\sigma(x_0, \ldots, x_{n-1})$ is a $\tau_{\Phi}$-term, $i < n$ and for some $t$ then $(a) \Rightarrow (b)$ where:
  
  (a) if $J$ is a linear order and $(M, \bar{a}) = \text{GEM}(J, \Phi)$ and $s_0 \not\approx ldot s < s_{n-1}$ and there is a function symbol $F$ (or just a term) such that $F \in \tau_{\Phi}$ has arity $n - 1$ and if $s_0 < I \ldots < I \ldots s_{n-1}, J, (M, \bar{a})$ are as above then

\[
F^M(a_0, \ldots, a_{n-1}) = \sigma^M(a_0, \ldots, a_{n-1}).
\]

§ 2(B). Example: Unsuperstability.

The following example illustrates the application of this method. We first fix $K_\omega$ (see §3) as the class of index models and fix a formula $\varphi_{tr}$ (see §5 below); note that we shall prove (for regular uncountable cardinals, see §7(1), §(2E) here; more is said in §7(2) which is proved in [Sh:331]) that for any pairs $I, J \in K_\omega$ $\varphi_{tr}(\bar{x}, y)$-unembeddable in $J$. In §9 we apply this to unsuperstable $T$. Lastly, in §11 below we choose for each $I \in K_\omega$ a reduced separable Abelian $p$-group $G_I$ which is representable in $\mathcal{M}_\omega(I)$. In §13 below we show that: [If $I$ is $\varphi_{tr}$-unembeddable in $J$ implies $G_I \not\approx G_J$]; thus the number of reduced separable Abelian $p$-groups of cardinality $\lambda$ is at least as great as the number of trees in $K_I$ with cardinality $\lambda$ which are pairwise $\varphi_{tr}$-unembeddable. Here we prove in §(1) that for any regular uncountable $\lambda$ that $2^\lambda$ is the number. We showed in §13 that this number is $2^\lambda$ for regular $\lambda$ and many singulars. But as said in §13 for every uncountable $\lambda$ we get $2^\lambda$ pairwise non-isomorphic such groups in $\lambda$, using $G_I$ as below.

We may like to strengthen “$G_I \not\approx G_J$” to “$G_I$ not embeddable in $G_J$”. Doing this depends on two points. One concerns singular cardinals, for them the needed family of $I \in K_\lambda$ exists by §7(2) which is proved only in [Sh:331]. The second point depends on the exact notion of embeddability we use; here we use so called “pure embeddings”, see §7(4) (we shall return to this in [Sh:331, 3.22]).

Example 2.6. For the class of $I \in K_\omega$ we let:

\[
\varphi_{tr}(x_0, x_1 : y_0, y_1) := [x_0 = y_0] \text{ and } P_\omega(x_0) \text{ and } \bigvee_{n<\omega} [P_n(x_1) \text{ and } P_n(y_1) \text{ and } P_{n-1}(x_1 \cap y_1)] \text{ and } [x_1 < x_0 \land y_1 \not\approx y_0] \text{ and } y_1 <_{lx} x_1.
\]
in other words, when for transparency we restrict ourselves to standard $I \subseteq \omega^2 \lambda : x_0 = y_0 \in {}^\omega \lambda$, and for some $n < \omega$ and $\alpha < \beta < \lambda$ we have

$$x_1 = (x_0 | n)^\alpha x_0$$

and

$$y_1 = (x_0 | n)^\beta$$

We quote

Theorem 2.7. Let $K = K_\omega$, trees with $\omega + 1$ level.

1) If $\lambda > \mu$ is regular, then $K$ has the strong $(2^\lambda, \lambda, \mu, \kappa_0)$-bigness property for $\varphi = \varphi_\kappa(\bar{x} | 2^\kappa; \bar{y} | 2^\kappa)$.\[1A\] We can add “full (strong)”.\[2\] On this, the existence, see [Sh:331, j2(2)] we can prove this.

2) If $\lambda > \mu$ then $K$ has the full strong $(\lambda, \lambda, \mu, \kappa_0)$-bigness property for $\varphi = \varphi_\kappa(\bar{x} | 2^\kappa; \bar{y} | 2^\kappa)$.

Proof. 1) Let $S_* = \{ \delta < \lambda : \mathrm{cf}(\delta) = \kappa_0 \}$ and for each $\delta \in S_*$ let $\eta_\delta \in {}^\omega \delta$ be increasing with limit $\delta$. Now for $S \subseteq S_*$ let $I_\delta = \{ \eta_\delta : \delta \in S \} \cup {}^{\omega^2} \lambda$. Now we consider $I_\delta$ as a member of $K_\omega^\kappa$ as usual.

The main point is:

[\[\Box\] if $S_1, S_2 \subseteq S_*$ and $S_1 \setminus S_2$ is a stationary subset of $\lambda$, then $I_{\delta_1}$ is $\varphi_\kappa$-unembeddable into $I_{\delta_2}$.]

Why is $\Box$ true? Let $f : I_\delta \to \mathcal{M}_\mu(I_{\delta_2})$ and $<_2$ a well ordering of $\mathcal{M}_\mu(S_2)$, let $\chi$ be such that $x = \{ S_1, S_2, I_\delta, \mathcal{M}_\mu(S_2) ; f, <_2 \}$ belongs to $\mathcal{F}(\chi)$. Choose a $\langle \chi \rangle$-increasing continuous sequence $(N_\alpha : \alpha < \lambda)$ such that $N_\alpha \times (\mathcal{M}(\chi), <) = (\lambda, \omega, <)$. Let $E = \{ \delta < \lambda : \delta$ is a limit ordinal such that $N_\delta \cap \lambda = \delta \}$, clearly a club of $\lambda$. But by the assumption of $\Box$, $S_1 \setminus S_2$ is stationary, hence we can find $\delta \in S_1 \cap E \setminus S_2$. Now as $N_\delta \cap \lambda = \delta$, there is $\varepsilon \in \delta$ and $n < \omega$ such that $\eta_\delta(n) \in N_\varepsilon$ and $N_\varepsilon \cap \lambda \subseteq \eta_\delta(n)$. Having chosen $\eta_\delta$ and $n$ we choose $\beta = \eta_\delta(n)$ and let $\alpha = (N_{\varepsilon+1} \cap \lambda) \cap \beta$ be similar enough to $\beta$.

So $\Box$ holds. We know that there is a sequence $\langle \delta : \varepsilon < \lambda \rangle$ of pairwise disjoint stationary subsets of $S_*$ and for every $u \subseteq \lambda$ let

$$S^*_u = \bigcup \{ S_\varepsilon : \text{ for some } \zeta < \lambda, \varepsilon \in \{ 2\zeta, 2\zeta + 1 \} \text{ and } \varepsilon = 2\zeta + 2 \leftrightarrow \zeta \in u \}.$$ 

Clearly $u \neq v \subseteq \lambda \Rightarrow S^*_u \setminus S^*_v$ is a stationary subset of $\lambda$ so we are done by $\Box$.

1A) By §(2D) and proof of part (1) we can prove this.

2) On this, the existence, see [Sh:331, j2(2)] (which we deduce from [Sh:331, b11(2)])

Remark 2.8. In [E5] we choose the last cardinal $\kappa_0$ as $\kappa_0$. There is interest in choosing $\kappa > \kappa_0$, but we shall not deal with it here, see [Sh:E81].

The connection of the bigness properties from [E2] to the results on $\hat{I}(\lambda, T_1, T)$ is done by:

Claim 2.9. Assume that
(a) $\Phi, \varphi_n$ are as in the conclusion of §2.11(1), $\mu \geq |\tau_\Phi| + \aleph_0$.

(b) $I, J \subseteq K_\nu^\omega$, $I$ is strongly $\varphi_n$-unembeddable into $J$ for $\tau_\mu, \aleph_0$, 

(c) $\tau_0 \subseteq \tau_\Phi$ is a vocabulary including that of the $\varphi_n$'s.

Then $GEM_\nu(I, \Phi)$ cannot be elementarily embedded into $GEM_{\tau_\nu}(J, \Phi)$. Moreover, no function from $GEM(I, \Phi)$ into $GEM(J, \Phi)$ preserves the formulas $\pm \varphi_n$ (for $n < \omega$).

Proof. Straightforward but we elaborate. Let $f$ be a function from the model $M_I = GEM(I, \Phi)$ into $M_J = GEM(J, \Phi)$ which preserve $\pm \varphi_n$; and let $\langle a_s : s \in I \rangle$ witness this; by §2.4(2) there is a function $g$ from $M_2$ into $M(J)$ which is a $\{ \pm \varphi_n : n < \omega \}$-representation.

Define a function $h : I \to f(g(s))(\mathcal{M}_\mu(J))$ by $h(s) = g(f(a_s))$ for $s \in I$.

Recalling ”$I$ is $\varphi_k$-unembeddable into $\mathcal{M}_\mu(J)$” there are $\eta = x_1 = x_2 \in P_n^\mu, n \leq \omega, \nu \in P_n^\mu$ and $y_1 \in \mathcal{U} y_2 \in \mathcal{U} \langle \nu \rangle$ such that $y_2 \prec \eta$ and $(h(\eta), h(y_2), (\eta, h(y_1))]$ are similar.

But by the choice of $\Phi, M_2 \models \varphi_n[a_n, a_{y_2}]$ hence by the choice to $f, M_2 \models \varphi_n[f(a_n), f(a_{y_2})]$ and $\varphi_n[f(a_n), f(a_{y_2})]$ by the choice of $g$, $(g \circ f(a_n), g \circ f(a_{y_2}))$ cannot be similar, contradiction.\[\square\]

§ 2(C). Example: Separable reduced Abelian $\hat{p}$-groups.

Discussion 2.10. We present the definition of this class of groups in §2.11(1),(2); see on it in [Yed. 3], [Yed. 4], [Yed. 12] and [Yed. 12]; but no need to read any of them.

From out point of view, this class is closely related to $K_\nu^\omega$. One way to express it is to derive a tree with $(\omega + 1)$ levels from such a group $G$: the $n$-th level consists of $G/E_n$ where $E_n$ is the following equivalence relation on $G : x \equiv y$ if $G \models (\exists z)(p^n z = x - y)$ and the $\omega$-th level consists of $\{ x \}$ for $x \in G$; the order is the inverse of inclusions. Of course, this is not a good representation; there is much redundancy. For example, $G/E_2$ is just a vector space over the field with $\hat{p}$ elements, so we better replace it by a basis. This motivates §2.11(3),(4).

In more detail, we can explicate $y_n^m/E_m$:

$$E_1 \quad y_n^m = x_n y_{nm+1} + \hat{p} y_{n+1}$$

$$= x_n y_n + \hat{p} x_n y_{n+1} + \hat{p} y_{n+2}$$

$$= x_n y_n + \hat{p} x_n y_{n+1} + \hat{p} y_{n+2}$$

$$= x_n y_n + \hat{p} x_n y_{n+1} + \hat{p} x_n y_{n+2}$$

So for $m \geq n$

$$E_2 \quad y_n^m = \sum_{\ell=n}^{m} \hat{p}^{n-\ell} x_{\ell} + \hat{p} y^{m-n} y_{n}$$

$$E_3 \quad y_n^m \text{ belongs to } \left\{ \sum_{\ell=n}^{m-n} \hat{p}^{n-\ell} x_{\ell} \right\}/E_{m-n}.$$
• if \((\eta : \ell \leq \ell_*\rangle\) are pairwise distinct members of \(P^I_n\) and \(k \ell \in \{1, \ldots, \hat{p}-1\}\) for \(\ell \leq k\) then \(\Sigma\{k\ell \hat{p}^nx_{\eta}\ : \ \ell \leq \ell_*\}\) is not \(E_n\)-equivalent to any member of \(\mathbb{G}_n\).

(See more in [Sh:331, §3]; as \(p\) denote types we use \(\hat{p}\) for prime numbers.)

**Definition 2.11.** 1) A separable reduced Abelian \(\hat{p}\)-group \(\mathbb{G}\) is a group \(\mathbb{G}\) which satisfies (we use additive notation):

(a) \(\mathbb{G}\) is commutative (that is “Abelian”),

(b) for every \(x \in \mathbb{G}\) for some \(n, x\) has order \(\hat{p}^n\) (i.e., \(\hat{p}^nx\) is zero and \(n\) is minimal),

(c) \(\mathbb{G}\) has no divisible non-trivial subgroup (= is reduced),

(d) every \(x \in \mathbb{G}\) belongs to some 1-generated subgroup which is a direct summand of \(\mathbb{G}\) (= is separable).

2) Any such group is a normed space:

\[\|x\| = \inf \{2^{-n} : (\exists y \in \mathbb{G}) \hat{p}^ny = x\}.\]

3) For a tree \(I \in K_{\omega}^{\omega}tr\) we define the \(\hat{p}\)-group \(\mathbb{G}_I\) as follows, \(\mathbb{G}_I\) is generated (as an Abelian group) by 

\[\{x_\eta : \eta \in \bigcup_{n<\omega} P^I_n\} \cup \{y_\eta^n : \eta \in P^I_\omega \text{ and } n < \omega\},\]

freely except for the relations:

(a) \(\hat{p}^{n+1}x_\eta = 0\) for \(\eta \in P^I_n\)

(b) \(\hat{p}^{n+1}y_\eta^n = 0\) for \(\eta \in P^I_\omega\)

(c) \(y_\eta^n - \hat{p}y_\eta^{n+1} = x_\eta|n\).

4) For Abelian groups \(\mathbb{G}_1, \mathbb{G}_2\), an embedding \(f\) of \(\mathbb{G}_1\) into \(\mathbb{G}_2\) is pure when for every \(\lambda \in \mathbb{G}_i\) and \(n \geq 2, x\) is divisible by \(n\) in \(\mathbb{G}_1\) \iff \(f(x)\) is divisible by \(n\) in \(\mathbb{G}_2\).

**Discussion 2.12.** It is well known that \(\mathbb{G}_I\) is a reduced separable Abelian \(\hat{p}\)-group. Also note that we have essentially said

\[y_\eta^n = \sum \{\hat{p}^{\ell-n}x_{\nu_{\ell}} : \ell \text{ satisfies } n \leq \ell < \omega, \nu_{\ell} \in P^I_\ell \text{ and } \nu_{\ell} < \eta\}\]

(the infinitary sum is well defined as \(\mathbb{G}_I\) is a normed space). What do we need to apply our framework to the class of Separable reduced Abelian Groups? We need to prove \(\mathbb{G}_I\) is represented in \(I\) for \(I \in K^{\omega}_{\omega}tr\), done in [E59, 2.13] and to derive “no isomorphism of \(\mathbb{G}_I, \mathbb{G}_J\)” from “\(I\) is \(\varphi_{tr}\)-unembeddable into \(J\)”, done in [E59, 2.14].

Of course, we can replace “\(h\) is an isomorphism from \(\mathbb{G}_I\) onto \(\mathbb{G}_J\)”, e.g. by “\(h\) embeds \(\mathbb{G}_I\) into \(\mathbb{G}_J\) which preserves “\(x\) is not divisible by \(\hat{p}^{n}\)” for every \(n\).

It is easy to see that

**Fact 2.13.** \(\mathbb{G}_I\) is a reduced separable Abelian \(\hat{p}\)-group which is represented in \(\mathcal{M}(I)\).

We shall prove now
Claim 2.14. 1) If $I$ is $\varphi_{tr}$-unembeddable into $J$ then $G_I \not\cong G_J$.
2) Moreover there is no pure embedding of $G_I$ into $G_J$.

Proof. Let $g$ be an isomorphism from $G_I$ onto $G_J$ and $h : G_J \rightarrow \mathcal{M}(J)$, where $h$ witnesses that $G_J$ is representable in $\mathcal{M}(J)$.

Let $f : I \rightarrow G_I$ be:

$$f(\eta) = \begin{cases} \sum_{1 \leq \ell \leq \ell(\eta)} \hat{p}^{\ell-1} x_{\nu_\ell} & \text{if } \eta \in \bigcup_{n<\omega} P_n^I, \\ y_{\nu_0} & \text{if } \eta \in P_0^I. \end{cases}$$

So $(h \circ g \circ f) : I \rightarrow \mathcal{M}_{\omega,\omega}(J)$. Now we use the fact that $I$ is $\varphi_{tr}$-unembeddable into $J$.

So suppose $I \models \varphi_{tr}(\eta_0, \nu_0; \eta_1, \nu_1)$ and $h \circ g \circ f(\eta_0, \nu_0) \sim h \circ g \circ f(\eta_1, \nu_1)$.

Invoking the definition of $\varphi_{tr}$: for some $\eta := \eta_0 = \eta_1 \in P_0^I$ and for some $n$,

1. $\nu_1 \prec \eta_1$
2. $\nu_1 \in P_n^I$
3. $\nu_0 \in P_0^I$
4. $\nu_1|(n-1) = \nu_0|(n-1)$
5. $\nu_0(n-1) < \nu_1(n-1)$.

For $i = 0, 1$ let

$$z_{\nu_i} = \sum \{ \hat{p}^{\ell-1} x_{\nu} : \nu \prec \nu_i, \nu \in P_\ell^I \text{ and } 1 \leq \ell \leq n \}.$$

Now $G_I \models \hat{p}^n \text{ divides } (y_{\nu_0} - z_{\nu_0})^\omega$, hence, as $g$ is an isomorphism, $G_J \models \hat{p}^n \text{ divides } (g(y_{\nu_0}) - g(z_{\nu_0}))^\omega$, which means $G_J \models \hat{p}^n \text{ divides } (g \circ f(\eta) - g \circ f(\nu_0))$.

Similarly, $G_J \models \hat{p}^n \text{ does not divide } (g \circ f(\eta) - g \circ f(\nu_1))$, but $h \circ g \circ f((\eta_0, \nu_0)) \sim h \circ g \circ f((\eta_1, \nu_1)) \mod \mathcal{M}(J)$, a contradiction, proving Claim 2.14. □

§ 2(D). An Example: Rigid Boolean Algebras.

Example 2.15. We would like to build complete Boolean algebras without non-trivial one-to-one endomorphisms. How do we get completeness? We build a Boolean algebra, $B_0$ and take its completion. Even when $B_0$ satisfies the c.c.c. we need the term $\bigcup_{n<\omega} x_n$ to represent elements of the Boolean algebra from the “generators” $\{ \bar{a}_t : t \in I \}$.

Discussion 2.16. On rigidity we still can get considerable amounts of information by the general theory. When we try to construct many models of $K$ (no one embeddable into the others) we need

1. there are $2^\lambda$ index models $I$ of cardinality $\lambda$ each $\varphi_K(\bar{x}, \bar{y})$-unembeddable into any other.
But when you intend to construct rigid, indecomposable, etc., you need:

(∗∗) there are \( \{ I_\alpha \in K : \alpha < \lambda \} \), \( I_\alpha \), \( \varphi \)-unembeddable into \( \sum I_\beta \) (and \( I_\alpha \) has cardinality \( \lambda \)).

Why?

Example 2.17. Constructing Rigid Boolean Algebras. (See more, and for more details, in [Sh:511, §2].) For \( I \in K^{\omega}_r \) let \( BA_{\alpha}(I) \) be the Boolean Algebra freely generated by \( \{ a_\eta : \eta \in I \} \) except the relations

\[ a_\eta \leq a_\nu \text{ when } \nu \in P^I_\omega, n < \omega, \eta = \nu \upharpoonright n. \]

First, choose a sequence \( \{ I_\alpha : \alpha < \lambda \} \) of members of \( K^{\omega}_r \) each of cardinality \( \lambda \). Naturally, we choose \( I_\alpha \) for \( \alpha < \lambda \) such that \( I_\alpha \) is \( \varphi_{tr} \)-unembeddable into \( \sum I_\beta, |I_\alpha| = \lambda \).

We shall choose a sequence \( \langle B_i, a_j : i \leq \lambda, j < \lambda \rangle \) such that \( B_i \) is a Boolean algebra, \( \subseteq \) increasingly continuous with \( i, a_i \in B_i \), and if \( i < \lambda \) and \( a \in B_i \setminus \{ 0, 1 \} \) then \( a = a_i \) for some \( j \in [i, \lambda) \). Start with \( B_0 = BA_{\alpha}(I_0) \), then successively for some \( a_i \in B_i \), \( 0 < i < 1 \), take

\[ B_{i+1} = (B_i \upharpoonright (1 - a_i)) + ((B_i \upharpoonright a_i) * BA_{\alpha}(I_i)), \]

\[ B_\lambda = \bigcup_{i < \lambda} B_i = \{ a_i : i < \lambda \}. \]

(In such situations we say that \( B_{i+1} \) is a result of the \( BA_{\alpha}(I_i) \)-surgery of \( B_i \) at \( a_i \).)

That is, below \( 1 - a_i \) we add nothing and below \( a_i \) we use the free product of \( B_i \) at \( a_i \) and \( BA_{\alpha}(I_i) \).

The point is that each \( a \in B_\lambda \setminus \{ 0, 1 \} \) was “marked” by some \( I_\alpha \), (the \( \alpha \) such that \( a_\alpha = a \)). Now \( BA_{\alpha}(I_\alpha) \) is embeddable into \( B_\lambda \upharpoonright a_\alpha \); but \( B_\lambda \upharpoonright (1 - a_\alpha) \) is weakly represented in \( \mathcal{M}(\sum I_\beta \downarrow I \beta) \). So for no automorphism \( f \) of \( B_\lambda \) do we have, \( f(a_\alpha) \leq 1 - a_\alpha \), which suffices to get “\( B_\lambda \) is rigid”; in fact, it has no one-to-one endomorphism. If we are trying to get stronger rigidity and/or \( B_\lambda \models \text{ c.c.c.} \), and/or \( B_\lambda \) is complete, we may have to change \( K^{\omega}_r \) and/or \( \varphi_{tr} \).

This illustrates the need for some of the complications in definition 2(E), 2(F). E.g., the weak representation and the uncountable \( \kappa \) (for complete Boolean Algebras). That is, if we like to get a complete Boolean Algebra, we may find a regular uncountable \( \kappa \), build a \( \kappa \)-c.c. Boolean Algebra \( B_1 \) satisfying the \( \kappa \)-c.c. and then use the completion \( B_2 \) of \( B_1 \). Now even if \( B_1 \) is represented in \( \mathcal{M}_{\mu, \kappa}(I), \mu = \mu^{<\kappa} \) then \( B_2 \) is naturally represented in \( \mathcal{M}_{\mu, \kappa}(I) \).

2E

§ 2(E). Closure sums.

As exemplified in §(2D), we like to have cases of the “\( K \) has full (strong) \( (\chi, \lambda, \mu, \kappa) \)-bigness for \( \varphi \)”, which means having sequences \( \{ I_\alpha : \alpha < \chi \} \) of members of \( K \) of cardinality \( \lambda \) such that \( I_\alpha \) is \( \varphi \)-unembeddable into \( \sum I_\beta : \beta \in \lambda \setminus \{ 0 \} \). For this, it is helpful to have classes \( K \) closed under sums, which is defined and investigated in this subsection.
The definition below (variants of closure under sums) are satisfied by the cases we shall deal with and enable us to translate results e.g. from the full (strong) \((\lambda,\lambda,\mu,\kappa)\)-bigness to the (strong) \((2^\lambda,\lambda,\mu,\kappa)\)-bigness.

Of course:

**Definition 2.18.** 1) We say that the class \(K\) of \(\tau\)-structures; with \(\tau\) a relational vocabulary for transparency, is closed under sums when for every sequence \((I_s : s \in S)\) of members of \(K\), pairwise disjoint, also \(I\) belongs to \(K\) where \(I\) is the \(\tau\)-structure which is the union of \((I_s : s \in S)\); that is the set of elements of \(I\) is the union of the sets of elements of \(I_s\) for \(s \in S\) and \(P^I = \cup\{P^I_s : s \in S\}\) for every predicate \(P\) from \(\tau\).

To deal with more general cases

**Definition 2.19.** 1) Let \(\tau\) be a vocabulary with no individual constant and no function symbols or with function symbols being interpreted as partial functions (so \((\exists y)(F(\bar{x}) = y)\) is really a predicate).

For \(\tau\)-models \(M_s\) for \(s \in S\) not necessarily pairwise disjoint, \(M = \sum_{s \in S} M_s\) is defined by:

(a) \(M\) is a \(\tau\)-model

(b) the universe of \(M\) is \(\{(s,a) : s \in S\text{ and } a \in M\}\)

(c) for a predicate \(P \in \tau, P^M = \cup\{P^M_s : s \in S\}\)

(d) similarly for function symbols.

2) We define sums for a class \(K\) of \(\tau_K\)-models with \(\tau_K\) with individual constants but only when \(M(\epsilon(\emptyset))\) for \(M \in K\) are pairwise isomorphic. That is, defining \(M = \sum_{s \in S} M_s\) we identify \((s,a),(t,b)\) where \(a = \sigma^M, b = \sigma^M\) and \(\sigma\) is a term of \(\tau\) with no free variables.

But in many cases which interest us, this is only almost true, hence we define:

**Definition 2.20.** 1) We say that \(K\) is almost \((\mu,\kappa)\)-closed under sums for \(\lambda\) and \(\psi\) where \(\psi = \psi(\bar{x},\bar{y}), \ell g(\bar{x}) = \ell g(\bar{y})\), when for every \(I_\alpha \in K\) (for \(\alpha < \alpha_0 \leq \lambda\), \(I_\alpha\) of cardinality \(\leq \lambda\), there are \(J, y, h_\alpha(\alpha < \alpha_0)\) such that:

(a) \(J \in K\) and \(|J| \leq \lambda\),

(b) \(h_\alpha : I_\alpha \rightarrow J,\) and for any \(x_0,\ldots,y_0,\ldots \in I_\alpha, I_\alpha \models \psi([x_0,\ldots],[y_0,\ldots])\)

implies \(J \models \psi([h_\alpha(x_0),\ldots],[h_\alpha(y_0),\ldots])\],

(c) \(g : J \rightarrow M_{\mu,\kappa}(\sum_{\alpha<\alpha_0} I_\alpha)\) satisfies, for any \(\gamma < \kappa, \bar{x}, \bar{y} \in \gamma J,\)

\(\Box_0\) if \(g(\bar{x}) \approx g(\bar{y})\) mod \(M_{\mu,\kappa}(\sum_{\alpha<\alpha_0} I_\alpha)\) then \(\bar{x} \approx \bar{y}\) mod \(M_{\mu,\kappa}(J)\).

2) We replace “almost” by “semi”, when in clause (c) above we weaken \(\Box_0\) to:

\(\Box_1\) if \(g(\bar{x}) \approx g(\bar{y})\) mod \((M_{\mu,\kappa}(\sum_{\alpha<\alpha_0} I_\alpha), R)\) then \(\bar{x} \approx \bar{y}\) mod \(M_{\mu,\kappa}(J),\) where we define

\(R = \{(\langle i,\eta \rangle, \langle j,\nu \rangle) : \eta \in I_i, \nu \in I_j\text{ and } i < j\} \subseteq (\sum_{\alpha<\alpha_0} I_\alpha) \times (\sum_{\alpha<\alpha_0} I_\alpha).\)

3) We add “strongly” to “close” in part (1) when we strengthen clause (c) to:
\( (c)^+ \): \( g : J \to \mathcal{M}_{\mu, \kappa}(\sum_{\alpha < \alpha_0} I_\alpha) \) such that for any well ordering \( <_0 \) of \( \mathcal{M}_{\mu, \kappa}(J) \) (as in \([5](d)\)), there is a well ordering \( <_1 \) of \( \mathcal{M}_{\mu, \kappa}(\sum_{\alpha < \alpha_0} I_\alpha) \) such that: for any \( \gamma < \kappa \) and \( \bar{x}, \bar{y} \in J \) and \( A \subseteq J \) of cardinality \( < \kappa \),
\[\square_2 \text{ if } g(\bar{x}) \approx g(\bar{y}) \mod (\mathcal{M}_{\mu, \kappa}(\sum_{\alpha < \alpha_0} I_\alpha), <_1), \text{ then } \bar{x} \approx \bar{y} \mod (\mathcal{M}_{\mu, \kappa}(J), <_0).\]

4) We add strongly in part (2) if we strengthen \( (c)^+ \), only using \( (\mathcal{M}_{\mu, \kappa}(\sum_{\alpha < \alpha_0} I_\alpha), <_1, R) \).

5) We may omit “(\( \mu, \kappa \))” above if \( \text{Rang}(g) \subseteq J \).

6) We say that \( K \) is essentially closed under sums for \( \lambda \) if in part (1) in addition, \( \text{Rang}(h_\alpha), \text{Rang}(g) \) are unions of equivalence classes of \( \langle R \rangle \) is from part (2).

Remark 2.21. We could have made, for example \( h_\alpha : I_\alpha \to \mathcal{M}_{\mu, \kappa}(J) \), or in the definition of sum expand by \( R \), without serious changes in the paper.

The following claim gives the obvious properites of “closure under sums” its holding for the classes we are mainly interested in and the use of closure similar for implications among bigness properties.

Claim 2.22. 0) “\( K \) is closed under sums” implies “\( K \) is essentially closed under sums”, which implies “\( K \) is almost closed under sums”, which implies “\( K \) is almost \( (\mu, \kappa) \)-closed under sums”.

In all above implications we can add “strongly” to both sides (when relevant, related).

1) If \( K \) is closed under sums, then the full (strong) \( (\chi, \lambda, \mu, \kappa) \)-\( \psi \)-bigness property implies the (strong) \( (\chi_1, \lambda, \mu, \kappa) \)-\( \psi \)-bigness property, where \( \chi_1 = \min\{2^\chi, 2^\lambda\} \).

2) In (1), instead of “\( K \) closed under sums” it is enough to assume that \( K \) is (strong) almost closed under sums for \( \lambda, \psi \).

3) The classes defined in \([5](2)\), \( (3), (6) \) have obvious monotonicity properties in \( \chi, \mu, \kappa \); and for all our \( K \), for \( \lambda \) too. For example
\[\chi \leq \chi' \Rightarrow [(\chi', \lambda, \mu, \kappa) \text{-bigness } \Rightarrow (\chi, \lambda, \mu, \kappa) \text{-bigness}] \]
\[\mu \leq \mu' \& \kappa \leq \kappa' \Rightarrow [(\chi, \lambda, \mu', \kappa') \text{-bigness } \Rightarrow (\chi, \lambda, \mu, \kappa) \text{-bigness}].\]

Proof. 0) Obvious.

1) So we assume \( K \) has the full \( (\chi, \lambda, \mu, \kappa) \)-\( \psi \)-bigness property. Without loss of generality \( \langle I_\alpha : \alpha < \chi \rangle \) are pairwise disjoint.

As \( K \) has the [strong] full \( (\chi, \lambda, \mu, \kappa) \)-\( \psi \)-bigness property, there are \( I_\alpha \in K \) (for \( \alpha < \chi \)), each of cardinality \( \lambda \), such that \( I_\alpha \) is \( \psi \)-unembeddable into \( \sum_{\beta \neq \alpha} I_\beta \).

Case 1: \( \chi \leq \lambda \).
For $U \subseteq \chi$ let $J_U = \sum_{\alpha \in U} I_\alpha$. Let $\mathcal{P}$ be a collection of subsets of $\chi$ such that $|\mathcal{P}| = 2^\chi$ and $U \neq V \in \mathcal{P} \Rightarrow U \nsubseteq V$. Suppose $U, V \in \mathcal{P}$, $f : J_U \rightarrow M(J_V)$. Choose $\alpha \in U \setminus V$. Thus $f|J_\alpha : I_\alpha \rightarrow M_{\mu, \kappa}(\sum_{\beta \neq \alpha} I_\beta)$ and the desired conclusion follows.

Case 2: $\lambda < \chi$.

Take a family $\mathcal{W}$ of subsets of $\lambda$, each of cardinality $\lambda$, such that

$$U \neq V \in H \Rightarrow U \nsubseteq V$$

and proceed as in Case 1.

2) As $K$ has the [strong] full $(\chi, \lambda, \mu, \kappa, \psi)$-bigness property, there are $I_\alpha \in K$ (for $\alpha < \chi$), each of cardinality $\alpha$, such that $I_\alpha$ is $\psi$-unembeddable into $\sum_{\beta \neq \alpha} I_\beta$. By the assumption of (2) (that $K$ is almost (strongly) closed under sums) for every $U \subseteq H, |U| \leq \lambda$ let $J_U, g_U, h^U_\alpha (\alpha  \in U)$ satisfy clauses (a), (b), (c) of Definition $2.20(1)$ for $\sum_{\alpha \in U} I_\alpha$. As in the proof of (1), it suffices to show:

$$(*)$$ if $U, V \subseteq \chi, |U| \leq \lambda, |V| \leq \lambda, U \setminus V \neq \emptyset$ and $f : J_U \rightarrow M_{\mu, \kappa}(J_V)$, then for some $\bar{a}, \bar{b} \in (g_U(x)(J_U), J_U \models \psi(\bar{a}, \bar{b})$ and $f(\bar{a}) \approx_A f(\bar{b})$ mod $M_{\mu, \kappa}(J_V), <)$ for the strong version.

Choose $\alpha \in U \setminus V$. In the strong case let $<_0$ be a well ordering of $M_{\mu, \kappa}(J_V)$ (as in $2.1(d), 2.20(3)$); choose a well ordering $<_1$ of $\sum_{\alpha \in U} I_\alpha$ as guaranteed by Definition $2.20(3)$; in the non-strong case let $<_0, <_1$ be the empty relations.

Now define

$$g^*_V : M_{\mu, \kappa}(J_V) \rightarrow M_{\mu, \kappa}(\sum_{\alpha \in V} I_\alpha)$$

by

$$g^*_V(\tau(x_0, \ldots)) = \tau(g_V(x_0), \ldots).$$

Consider the sequence of mappings:

$$I_\alpha \xrightarrow{h^U_\alpha} J_U \xrightarrow{f} M_{\mu, \kappa}(J_V) \xrightarrow{g^*_V} M_{\mu, \kappa}(\sum_{\alpha \in V} I_\alpha).$$

So $g^*_V \circ f \circ h^U_\alpha : I_\alpha \rightarrow M_{\mu, \kappa}(\sum_{\alpha \in V} I_\alpha)$. As $\sum_{\alpha \in V} I_\alpha$ is a submodel of $\sum_{\alpha \in V \setminus \alpha} I_\alpha$, also without loss of generality $M_{\mu, \kappa}(\sum_{\alpha \in V} I_\alpha)$ is a submodel of $M_{\mu, \kappa}(\sum_{\alpha \in V \setminus \alpha} I_\alpha)$. But we know that $I_\alpha$ is $\psi$-unembeddable into $\sum_{\alpha \in V \setminus \alpha} I_\alpha$. Hence there are $\bar{x}, \bar{y} \in I_\alpha$ such that:

(i) $I_\alpha \models \psi[\bar{x}, \bar{y}]$,

(ii) $g^*_V \circ f \circ h^U_\alpha(\bar{x}) \approx g^*_V \circ f \circ h^U_\alpha(\bar{y})$ mod $(M_{\mu, \kappa}(\sum_{\alpha \in V} I_\alpha), <_1)$. 
By (i) and clause (b) from (1) of (3),
(iii) \( J_U \models \psi[\bar{x}', \bar{y}'] \), where \( \bar{x}' = h^U_\alpha(\bar{x}), \bar{y}' = h^U_\alpha(\bar{y}) \).

By (ii) and the definition of \( \bar{x}', \bar{y}' \),
(iv) \( g^*_\nu(f(\bar{x}')) \approx g^*_\nu(f(\bar{y}')) \mod (M_{\mu, \kappa}(\sum_{i \in V} I_i), <_1) \).

By (iv), clause (c) of (1) or clause (c) of (3), the definition of \( g^*_\nu \), and of \( g^*_\nu \),
(v) \( f(\bar{x}') \approx f(\bar{y}') \mod (M_{\mu, \kappa}(J_\nu), <_0) \).

So we have proved (*) (by (iii) and (v)), which suffices.

3)-6) Left to the reader. \( \square \)

Claim 2.23. The following classes are almost (and also semi) \((\mu, \kappa)\)-closed under sums for \( \lambda \)

(a) \( K_{\alpha_0} \) (the class linear orders)
(b) \( K^*_{\alpha_0} \) (trees with \( \omega + 1 \) levels)
(c) \( K^\kappa_{\alpha_0} \) (trees with \( \kappa + 1 \) levels)
(d) \( K_{\text{org}} \) (ordered graphs).

Proof. Case (a)
If \( \langle I_\alpha : \alpha < \alpha_0 \rangle \) is a sequence of linear orders then we let:
(i) \( J = \bigcup \{ \{ \alpha \} \times I_\alpha : \alpha < \alpha_0 \} \)
(ii) \( (\alpha_1, t_1) <_J (\alpha_2, t_2) \) if and only if \( \alpha_1 < \alpha_2 \lor (\alpha_1 = \alpha_2 \land t_1 <_{I_{\alpha_1}} t_2) \)
(iii) \( h_\alpha : I_\alpha \to J \) is \( h_\alpha(t) = (\alpha, t) \)
(iv) \( g : J \to \sum_{\alpha < \alpha_0} I_\alpha \) is the identity.

Now check
Case (b):
Given \( \langle I_\alpha : \alpha < \alpha_0 \rangle \) the unique we identify the member of \( P^{J_{\alpha_0}}_0 \) for \( \alpha < \alpha_0 \) but make then otherwise disjoint and take the union.

Case (c):
Similar to case (b).

Case (d):
Similar to case (a). \( \square \)

Another way to present those matters is to do it around the following definition and claim. That is, we note (in (2) of (3)) another sufficient condition for implications of the form “if \( I \) is unembeddable into \( J_2 \) then it is unembeddable into \( J_1 \).

Definition 2.24. 1) We say that \( J_2 \) does \((\mu, \kappa)\)-dominate \( J_1 \) when there is a function \( g \) from \( M_{\mu, \kappa}(J_1) \) into \( M_{\mu, \kappa}(J_2) \) such that: if \( \xi < \kappa \) and \( a, b \in \xi(M_{\mu, \kappa}(J_1)) \) and \( g(a) \equiv g(b) \mod M_{\mu, \kappa}(J_2) \) then \( a \equiv b \mod M_{\mu, \kappa}(J_1) \).

2) We say that \( J_2 \) strongly \((\mu, \kappa)\)-dominate \( J_1 \) when:
Claim 2.25. If $I$ is [strongly] $\varphi(x,y)$-embeddable into $J_2$ and $J_2$ [strongly] $(\mu,\kappa)$-dominate $J_1$ then $I$ is [strongly] $\varphi(x,y)$-embeddable into $J_1$.

Proof. First, apply Definition 2.24 without the “strong”; we have to prove that $I$ is $\varphi(x,y)$-embeddable into $J_2$ for $\tau_{\mu,\kappa}$. So assume that $f_1 : I \to V_{\mu,\kappa}(J_1)$ and we should find $\bar{a}, \bar{b} \in \tau_{\mu,\kappa}$ as in Definition 2.24(1). By the assumption of 2.25 there is a function $g : V_{\mu,\kappa}(J_1) \to V_{\mu,\kappa}(J_2)$ as in Definition 2.24(1). So $f_2 := g \circ f_1$ is a well defined function from $I$ into $V_{\mu,\kappa}(J_2)$, so recalling that we know “$I$ is $\varphi(x,y)$-embeddable into $J_2$ for $\tau_{\mu,\kappa}$”, it follows that there are sequences $\bar{s}, \bar{t}$ from $\tau_{\mu,\kappa}$ such that:

1) $f_2(\bar{s}), f_2(\bar{t})$ are similar in $V_{\mu,\kappa}(J_2)$

2) $I \models \varphi[\bar{s}, \bar{t}]$.

We now apply our assumption “$J_2, (\mu,\kappa)$-dominate $J_1$ as exemplified by the function $g$” to the sequences $f_1(\bar{s}), f_2(\bar{t})$ in $\tau_{\mu,\kappa}(J_1)$. The assumption “$g(f_1(\bar{s}) \not\equiv g(f_2(\bar{t}))$ mod $V_{\mu,\kappa}(J_2)$” holds by the choice of $\bar{s}, \bar{t}$. Hence the conclusion in 2.24 holds which means that $f_1(\bar{s}) \equiv f_1(\bar{t})$ mod $V_{\mu,\kappa}(J_1)$ so $\bar{s}, \bar{t}$ are as required.

The proof of the strong version is similar.

§ 2(F). Back to linear orders.

As we have remarked in the introduction to this paper, results on trees can be translated to results on linear orders; this is done seriously in [Sh:363]. Originally this was neglected as the results on unsuperstable $T$ (and trees with $\omega + 1$ levels) give the results on unstable theories (and linear orders). Anyhow, now we deal with the simplest case parallel to [Sh:363, Ch.VIII,2.1], see more in [Se:ES1].

Definition 2.26. 1) For any $I \subseteq K_\kappa^\kappa$ we define $\text{or}(I)$ as the following linear order (See Def. 2.21(4)).

definition of elements is chosen as $\{\langle t, \ell \rangle : \ell \in \{1, -1\}, t \in I\}$

the order is defined by $(t_1, \ell_1) < (t_2, \ell_2)$ if and only if $t_1 \not\triangleleft t_2 \land \ell_1 = 1$ or $t_2 \not\triangleleft t_1 \land \ell_2 = -1$ or $t_1 = t_2 \land \ell_1 = -1 \land \ell_2 = 1$ or $t_1 <_{\text{incomparable}} t_2 \land (t_1, t_2)$ are 4-incomparable.

2) Let $\varphi_{or}(x_0, x_1; y_0, y_1)$ be the formula $x_0 < x_1 \land y_1 < y_0$.

3) Let $\varphi_{\text{tr}}(x_0, x_1; y_0, y_1)$ be (this is for $K_\kappa^\kappa$, for $\kappa = 0$ see example 2.5)

\[
\varphi_{\text{tr}}(x_0, x_1; y_0, y_1) := [x_0 = y_0 \land P_\kappa(x_0) \land \bigvee_{\varepsilon < \kappa} [P_{\varepsilon + 1}(x_1) \land P_{\varepsilon + 1}(y_1) \land P_\kappa(x_1 \cap y_1)] \land [x_1 < x_0 \land \neg(y_1 < y_0)] \land y_1 <_{\text{incomparable}} x_1].
\]

Claim 2.27. 1) Assume that $I, J \subseteq K_\kappa^\kappa$.

(a) If $I$ is strongly $\varphi_{or}^\kappa$-embeddable for $\tau_{\mu,\kappa}$ into $J$ then $\text{or}(I)$ is strongly $\varphi_{or}^\kappa$-embeddable for $\tau_{\mu,\kappa}$ into $\text{or}(J)$
(b) similarly without "strongly".

2) If $K^\omega_{\text{or}}$ has the strong $(\chi, \lambda, \mu, \kappa)$-bigness property then $K_{\text{or}}$ has the strong $(\chi, \lambda, \mu, \kappa)$-bigness property.

3) In part (2) we may add "full" and/or omit "strong" in the assumption and the conclusion.

Proof. The main point is that:

(*) if $I \models \varphi^\iota((x, 0), (x_1, 1); (y_0, 1), (y, 1))$ then or $(I) \models \varphi((x_0, 1), (x_1, 1); (y_0, 1), (y, 1))$.

But (*) is easy to verify. □

Remark 2.28. 1) We deal mainly with $K^\omega_{\text{or}}$, recall $\text{Sh}^{\omega}_{\text{or}}$, i.e. see more in $\text{Sh}^{331}_{\text{or}}$, p2(2), so by it we know that $K^\omega_{\text{or}}$ has the full strong $(\lambda, \mu, \kappa)$-bigness property when $\mu < \lambda$.

2) For $\kappa$ regular uncountable, there are parallel results, noting that obviously $K^\omega_{\text{or}}$ has the full strong $(\chi, \lambda, \mu, \kappa)$ when $\lambda$ is regular $|\alpha| < \kappa$ and every $\alpha < \lambda$ and $\lambda < \chi$.

It seems reasonable to conjecture that the parallel of $\text{Sh}^{331}_{\text{or}}$, p2(2)] holds, but we have not tried to work on it, see part (3) of the remark.

3) The results below (on $\varphi_{\text{or}, \alpha, \beta, \pi}$) seem to me a natural step but have actually set down to phrase and prove them for Usvyatsov-Shelah $\text{Sh}^{\omega}_{\text{Sh}:331}$.

4) Even for $\kappa = \aleph_0$ we do not deal with $\lambda$ singular below, it seems reasonable that this, i.e., the parallel of $\text{Sh}^{331}_{\text{or}}, \S 1] holds, but the results below are more than sufficient for its purpose, as for $\chi > \mu$ singular we can use the result here for $(\chi, \lambda, \mu, \kappa)$ for any regular $\lambda \in (\mu, \chi)$.

5) In $\text{Sh}:331$ we use $\alpha, \beta$ well orders.

It seems reasonable that we can say more for a more general case but again this was not required.

6) We use freely the obvious observation $\text{Sh}^{\omega}_{\text{Sh}:331}$ below (see also $\text{Sh}:331$). Note that the “essentially” version dealt with in $\text{Sh}^{\omega}_{\text{Sh}:331}$ was not covered by $\text{Sh}^{\omega}_{\text{Sh}:331}.$

Observation 2.29. 1) $K_{\text{or}}$ is essentially closed under sums for $\lambda$ and $\varphi_{\text{or}},$ recalling Definitions $\text{Sh}:27(6), \text{Sh}:27(6).

2) Similar for $\varphi_{\text{or}, \alpha, \beta, \pi}$ defined below.

We have seen above how from a “complicated” sequence of members of $K^\omega_{\text{or}}$ we can derive one of the members of $K_{\text{or}}.$ But this does not indicate that linear order can be reduced to this case. We know that we can derive linear orders from members of $K^\omega_{\text{or}}$ for each $\kappa > \aleph_0,$ but clearly the class $K^\omega_{\text{or}}$ is more complicated than the class $K^\omega_{\text{tr}}.$ Anyhow we have suggested a way to express in our framework that $K_{\text{or}}$ is complicated, instead of $\varphi_{\text{or}}(\bar{x}, \bar{y})$ saying $x_0 < x_1 \land y_2 < y_0,$ below we use a possibly infinite $\bar{x}$ and $\varphi$ says $\bar{x} = (x_i : i < \alpha)$ is increasing, $(y_{\pi(i)} : i < \alpha)$ is increasing, where $\pi$ is a permutation of $\alpha.$

Note that $\text{Sh}^{\omega}_{\text{Sh}:331}$ the results of $K^\omega_{\text{or}}$ for regular $\lambda \geq \mu.$

Definition 2.30. We define the following (quantifier free infinitary) formulas for the vocabulary $\{<\}$. For any ordinal $\alpha,$ $\beta$ and a one-to-one function $\pi$ from $\alpha$ onto $\beta,$ and we let $\varphi_{\text{or}, \alpha, \beta, \pi}(\bar{x}, \bar{y})$ where $\bar{x} = \bar{x}^\beta = (x_i : i < \alpha)$ and $\bar{y} = \bar{y}^\beta = (y_i : i < \alpha),$ be

$$\bigwedge\{x_i < x_j : i < j < \alpha\} \text{ and } \bigwedge\{y_i < y_j : i, j < \alpha \text{ and } \pi(i) < \pi(j)\}.$$
Claim 2.31. Assume $\chi \geq \lambda = \text{cf}(\lambda) > \mu^{<\kappa}, \kappa = \text{cf}(\kappa)$ and $\gamma < \lambda \Rightarrow |\gamma|^{<\kappa} < \lambda$.
1) For $(\alpha, \beta, \pi)$ as in Definition 2.30, such that $\alpha, \beta \leq \lambda$, the class $K_{\alpha}$ has the full strong $(\lambda, \chi, \mu, \kappa)$-bigness property for $\varphi_{\alpha, \beta, \pi}(\bar{x}, \bar{y}).$
2) For $(\alpha, \beta, \pi)$ as in Definition 2.30 such that $\alpha, \beta \leq \lambda$, the class $K_{\beta}$ has the strong $(2^\lambda, \chi, \mu, \kappa)$-bigness property for $\varphi_{\alpha, \beta, \pi}$.
3) In fact in both part (1) and (2) we can find examples which satisfies the conclusion for all triples $(\alpha, \beta, \pi)$ as there simultaneously.

Proof. 1) By 2.18 below because there are $\lambda$ pairwise disjoint stationary sets $S \subseteq S_{\lambda \otimes \delta}$, and it belongs to $S_{\lambda \otimes \delta}$.
2) By part (1) and 2.29(1) and 2.21(1).
3) Check the proof.

Claim 2.32. Assume $\kappa = \text{cf}(\kappa) \leq \mu, \mu^{<\kappa} \leq \lambda = \text{cf}(\lambda) \leq \lambda_1, \kappa \leq \partial = \text{cf}(\partial) < \lambda$ and $\gamma < \lambda \Rightarrow |\gamma|^{<\kappa} < \lambda$.

If $I, J \in K_{\alpha}$ satisfies $\oplus$ below and $\alpha, \beta, \lambda$ and $\pi$ is a one-to-one function from $\alpha$ onto $\alpha$, then (recalling Definition 2.26) $\text{or}(I)$ is strongly $\varphi_{\alpha, \alpha^*, \pi}(\bar{x}, \bar{y}^*)$-unembeddable for $(\mu, \kappa)$ into $\text{or}(J)$ where:

- (a) $S_1, S_2 \subseteq S^\alpha$ such that $S_1 \setminus S_2$ is a stationary subset of $\lambda$.
- (b) $\eta = \langle \eta_i : \delta \in S_1 \cup S_2 \rangle$ where $\eta_i$ is an increasing sequence of ordinals $< \delta$ with limit $\delta$ of length $\partial$.
- (c) for every $\alpha < \lambda$ the set $\{\eta_i[i] : \delta \in S_1, i < \partial \text{ and sup } \text{Rang}(\eta_i[i]) \leq \alpha \}$ has cardinality $< \lambda$; actually follows.
- (d) $I \in K_{\alpha^*}$ is $\{\eta_i[i] : i \leq \partial, \delta \in S_1 \} \cup \{(\alpha) : \alpha < \lambda_1\}$.
- (e) $J \in K_{\alpha^*}$ is $\{\eta_i[i] : i \leq \partial, \delta \in S_1 \} \cup \{(\alpha) : \alpha < \lambda_1\}$.

Proof. By 2.25 it is enough to prove that $\text{or}(I)$ is strongly $\varphi_{\alpha, \alpha^*, \pi}(\bar{x}, \bar{y}^*)$-unembeddable into $\text{or}(J)$.

So let $f$ be a function from $\text{or}(I)$ into $\text{or}(J)$ so actually a function from $I \times \{1, -1\}$ into $\text{or}(J)$, and let $\chi$ be large enough. Let $N = \{N_\alpha : \alpha < \lambda\}$ be an increasing continuous sequence of elementary submodels of $(\mathbb{M}^{\alpha}, \in)$ such that $I, J, \eta, \eta$, $\text{or}(\chi), (\partial, \delta) \in N_1$ and $N_{\alpha+1} \cap \lambda \in \lambda_1$. $N_{\alpha+1} \ni (\alpha + 1)$ for every $\alpha; \lambda$, and it happens $“\alpha, \beta, \pi \in N_0”$ is not needed. So $E = \{\delta < \lambda : N_\delta \cap \lambda = \delta\}$ is club of $\lambda$ hence we can choose $\delta \in E \cap S_1 \cup S_2$.

For any $\eta \in I$, clearly $f(\langle \eta, 1 \rangle)$ is well defined and $\text{or}(\chi)$ is well defined so 2.26) $f(\langle \eta, 1 \rangle) = \sigma_{\eta}(\nu_\eta)$ where $\sigma_{\eta}$ is a $\tau_{\mu, \kappa}$-term, $\nu_\eta = (\nu_\eta, \tau_{\eta, \epsilon}) : \epsilon < \epsilon_\kappa$, $\nu_{\eta, \epsilon} \in J$ and $\nu_{\eta, \epsilon} \subseteq \{1, -1\}, \epsilon_\kappa < \kappa$.

Let $\epsilon_\kappa = \epsilon_{\eta_1, \epsilon} = \epsilon_{\eta_1, \epsilon}, i^*_\epsilon = \text{lg}(\nu_{\eta_1, \epsilon})$, so $i^*_\epsilon \leq \partial$ for $\epsilon < \epsilon_\kappa$ and let $j^*_\epsilon = \text{sup}\{j \leq i^*_\epsilon : \text{sup } \text{Rang}(\nu_{\eta_1, \epsilon}[j]) < \delta\}$. By our assumption $j^*_\epsilon = \partial$ implies $i^*_\epsilon = \partial$ hence as $\delta \in S_2$ it follows that $\text{sup } \text{Rang}(\nu_{\eta_1, \epsilon}[j^*_\epsilon]) < \delta$ hence by clause (c) of the assumption $\nu_{\eta_1, \epsilon}[j^*_\epsilon] \subseteq N_3$. Also $\alpha < \partial \Rightarrow J \cap \alpha \subseteq N_{\alpha+1}$ because $N_3 \cap \lambda \in \lambda$, it has cardinality $< \lambda$ and it belongs to $N_{\alpha+1}$; also let $\nu^*_\epsilon = \nu_{\eta_1, \epsilon}[j^*_\epsilon]$, it too belongs to $N_3$.

So $\{\nu^*_\epsilon : \epsilon < \epsilon_\kappa\} \subseteq N_3$, and it has cardinality $< \kappa$ as $\alpha < \lambda \Rightarrow |\alpha|^{<\kappa} < \lambda$ and $\text{cf}(\partial) = \partial < \kappa$ it follows that $\nu^* \subseteq \{\nu^*_\epsilon : \epsilon < \epsilon_\kappa\} \subseteq N_3$.

Let $\nu = \{\epsilon < \epsilon_\kappa : j^*_\epsilon < i^*_\epsilon\}$. For $\epsilon \in \nu$ let $\alpha^* = \min(\nu_\eta \cap (\lambda + 1) \setminus \nu_{\eta_1, \epsilon}[j^*_\epsilon])$, so as above also $\alpha^* = (\alpha^* : \epsilon \in \nu_\eta) \subseteq N_3$.

Now for $\eta \in \partial > \lambda$ we define $\mathcal{B}_\eta$ as the set of $\beta \in S_1$ such that:
\[\begin{align*}
\text{(a) } & \quad \eta \triangleleft \eta_3 \\
\text{(b) } & \quad \sigma_{\eta_3} = \sigma, \text{ so } \epsilon_{\eta_3} = \epsilon_3 \\
\text{(c) } & \quad \lg(\nu_{\eta_3, \epsilon}) = \iota_3^* \text{ for } \epsilon < \epsilon_3 \\
\text{(d) } & \quad \nu_{\eta_3, \epsilon}(j_3^*) = \nu_3^* \text{ for } \epsilon < \epsilon_3 \\
\text{(e) } & \quad \iota_{\eta_3, \epsilon} = \iota_3 \text{ for } \epsilon < \epsilon_3
\end{align*}\]

Note

\(\oplus\) if \(\eta \triangleleft \eta_3\) then

\[\begin{align*}
\text{(a) } & \quad \delta \in \mathcal{B}_q \text{ and } \mathcal{B}_q \in \mathcal{N}_\delta \\
\text{(b) } & \quad \cf(\alpha_3^*) = \lambda \text{ for } \epsilon \in u_3 \\
\text{(c) } & \quad \delta \in \prod_{\epsilon \in u_3} \alpha_3^* \text{ then for arbitrarily large } \beta \in \mathcal{B}_q \text{ we have } \epsilon \in u_3 \Rightarrow \\
\text{(d) } & \quad \mathcal{B}_q \text{ is an unbounded subset of } S_1.
\end{align*}\]

[Why? Clause (a) directly. Why clause (b)? Clearly \(\nu_{\delta, \epsilon}(j_3^*) \leq \delta\) hence \(\nu_{\delta, \epsilon}(j_3^*) \in \lambda \setminus N_\delta\) but \(N_\delta \cap \lambda \in \lambda\) hence \(\cf(\alpha_3^*) = \lambda\) follows. Why clause (d)? Otherwise \(\sup(\mathcal{B}_q) < \lambda\) and it belongs to \(N_\delta\) because \(\mathcal{B}_q \in \mathcal{N}_\delta, \text{ hence } \sup(\mathcal{B}_q) \in N_\delta \cap \delta\) so \(\sup(\mathcal{B}_q) < \delta\) contradicting clause (a). Clause (c) is proved similarly.]

Next let \(\Lambda\) be the set of \(\eta \in \beta\lambda\) such that

\[\circ_\eta \text{ for every } \alpha \in \prod_{\epsilon \in u_3} \alpha_3^* \text{ there is } \beta \in \mathcal{B}_q \text{ such that } \epsilon \in u_3 \Rightarrow \nu_{\eta, \epsilon}(j_3^*) \in (\alpha_\epsilon, \alpha_\epsilon^*).\]

So

\[\begin{align*}
\text{(\ast)_1 } & \quad \eta_1 \triangleleft \eta_2 \land \eta_2 \in \Lambda \Rightarrow \eta_1 \in \Lambda \\
\text{(\ast)_2 } & \quad \epsilon \prec \kappa \Rightarrow \eta_3(\epsilon \in \Lambda).
\end{align*}\]

Hence

\[\text{(\ast)_3 for some } \eta_3 \in \Lambda \text{ the set } \mathcal{W} = \{\gamma \triangleleft \lambda : \eta_3^*(\gamma) \in \Lambda\} \text{ is an unbounded subset of } \lambda.\]

Let \(\langle \gamma_\zeta : \zeta < \lambda \rangle\) list \(\mathcal{W}\) in increasing order, and let \(\alpha_\zeta, \beta_\zeta \leq \lambda\) and \(\pi\) be a one-to-one function from \(\alpha_\zeta\) onto \(\beta_\zeta\).

Now first we choose \(\delta(1, \zeta) \in S_1\) by induction on \(\zeta < \alpha_\zeta\) such that:

\[\text{(\ast)_4 (a) } \quad \delta(1, \zeta) \in \mathcal{B}_{\eta_3^*(\gamma_\zeta)} \text{ i.e. } \gamma_\zeta \in \mathcal{W} \]

\[\text{(b) } \quad \text{if } \epsilon \in u_3 \text{ then } \nu_{\delta(1, \zeta), \epsilon}(j_3^*) \in \alpha_\zeta^* \text{ but is } \sup\{\nu_{\delta(1, \zeta), \epsilon}(j_3^*) : \xi < \zeta\}.\]

This is easy.

Second we choose \(\delta(2, \zeta) \in S_1\) by induction on \(\zeta < \beta_\zeta\) such that:

\[\text{(\ast)_5 (a) } \quad \delta(2, \zeta) \in \mathcal{B}_{\eta_3^*(\gamma_\zeta)} \text{ when } \pi(\xi) = \zeta \]

\[\text{(b) } \quad \text{if } \epsilon \in u_3 \text{ then } \nu_{\delta(2, \zeta), \epsilon}(j_3^*) \in \alpha_\zeta^* \text{ but is } \sup\{\nu_{\delta(2, \zeta), \epsilon}(j_3^*) : \xi < \zeta\}.\]

Let \(a = \langle \alpha_\zeta : \zeta < \alpha \rangle, \ b = \langle \beta_\zeta : \zeta < \alpha \rangle\) from \(\alpha I\) be chosen as follows: \(a_\zeta = (\eta_3(1, \zeta), 1), b_\zeta = (\eta_3(\pi(\xi), 1)\rangle\) for \(\zeta < \alpha\).

Now check, e.g.:

\[\text{(\ast)_6 } a(\zeta_1) < a(\zeta_2) \iff \gamma(\zeta_1) < \gamma(\zeta_2) \iff \gamma(1) < \zeta(2)\]
(*) $b_{\zeta(1)} \leq_{or(1)} b_{\zeta(2)}$ iff $\gamma_{\pi_{\zeta}(1)} < \gamma_{\pi_{\zeta}(2)}$ iff $\pi_{\zeta}(1) < \pi_{\zeta}(2)$. \hfill \Box
§ 3. Order Implies Many Non-Isomorphic Models

In this section (in a self contained way) we prove that not only the old result that any unstable (first order) $T$ has in any $\lambda \geq |T| + \aleph_1$, the maximal number ($2^\lambda$) of pairwise non-isomorphic models holds, but for example that for any template $\Phi$ proper for linear orders, if the formula $\varphi(x,y)$ with vocabulary $\tau$, linearly orders $\{a_s : s \in I\}$ in $EM_\tau(I, \Phi)$ (Ehrenfeucht-Mostowski model, see §1) for every $I$, then the number of non-isomorphic models of the form $EM_\tau(I, \Phi)$ of cardinality $\lambda$ up to isomorphism is $2^\lambda$ when $\lambda \geq |\tau_\Phi| + \aleph_1$.

Dealing with this problem previously, the author (in the first attempt [Sh:12]) excluded some of the cardinals $\lambda$ which satisfy $\lambda = |\tau_\Phi| + \aleph_1$ and in the second [Sh:c, Ch.VIII,§3], replaced the $EM_\tau(I, \Phi)$ with some kind of restricted ultrapower (of itself). Subsequently (in [Sh:100]) we proved that for some unsuperstable first order complete theory $T$, and a first order theory $T_1$ extending $T$, $|T_1| = \aleph_1$, $|T| = \aleph_0$, the class

$$PC(T_1, T) = \{ M : |\tau(M) : M \models T_1 \}$$

may be categorical in $\aleph_1$, “may be categorical” mean that some forcing extension this holds for some $T, T_1$; in fact if the original universe $V$ satisfies CH, we may choose $T, T_1$ in $V$.

We also prove there for $T = \text{the theory of dense linear order}$, that we may, i.e. in some forcing extension, have a universal model in $\aleph_1$ even though CH fails. We then thought that the use of ultrapower in [Sh:c, Ch.VIII,§3] was necessary. This is not true. (We thank Rami Grossberg for a stimulating discussion which directed me to this problem again).

By the present theorem we can get the theorem also for the number of models of $\psi \in \mathcal{L}_{\lambda^+\tau, \aleph_0}$ in $\lambda (\geq \aleph_0)$ when $\psi$ is unstable. Incidentally the proof is considerably easier (than in [Sh:c, Ch.VIII,§3]).

Note that we do not need to demand $\varphi(x,y)$ to be first-order; a formula in any logic is O.K.; it is enough to demand $\varphi(x,y)$ to have a suitable vocabulary. This is because an isomorphism from $N$ onto $M$ preserves satisfaction of such $\varphi$ and its negation. However, the length of $\bar{x}$ (and $\bar{y}$) is crucial. Naturally we first concentrate on the finite case (in §1–§3). But when we are not assuming this, we can, “almost always” save the result. In first reading, it may be advisable to concentrate on the case “$\lambda$ is regular”, $\varphi = \varphi(x,y)$ an asymmetric formula, $I$ a linear order.

³A § 3(A). Skeleton like sequence and invariants.

For this section, the notion “$\langle \bar{a}_t : t \in I \rangle$ is weakly ($\kappa$, $\varphi(x,y)$)-skeleton like inside $M''$” from Definition 1(3),(4) is central and in Definition 1 we can concentrate on it but it relies on 1(1) for the case $\Lambda = \{ \varphi(x,y), \psi(y,x) \}$, $J = \ell_\varphi(\bar{y}) M = \ell_\psi(\bar{x}) M$.

P2 Definition 3.1. Let $M$ be a model, $I$ an index model; for $s \in I$, $\bar{a}_s$ is a sequence from $M$, the length of $\bar{a}_s$ depends on the quantifier-free type of $s$ over $\emptyset$ in $I$ only; $\Lambda$ is a set of formulas of the form $\varphi(x, \bar{a})$, $\bar{a}$ from $M$, $\varphi = \varphi(x,y)$ a formula which has a vocabulary contained in $\tau(M)$ and $J$ a set of sequences from $M$. 
1) We say that \( \langle \bar{a}_s : s \in I \rangle \) is weakly \( \kappa \)-skeleton like inside \( M \) for \(^2\Lambda\) when: for every \( \varphi(x, \bar{a}) \in \Lambda \), there is \( J \subseteq I \), \( |J| < \kappa \) such that:

\[
\varphi(x, \bar{y}) \in \Lambda, \text{ if } s, t \in I \text{ and } \text{tp}_{\text{qf}}(t, J, I) = \text{tp}_{\text{qf}}(s, J, I) \text{ and } \ell g(\bar{a}_s) = \ell g(\bar{x}) \text{ then }
M \models \varphi[\bar{a}_s, \bar{a}] \equiv \varphi[\bar{a}_t, \bar{a}].
\]

2) Variants:

(a) If \( \Lambda = \{ \varphi(x, \bar{a}) : \varphi(x, \bar{y}_\varphi) \in \Delta \text{ and } \bar{a} \in \bar{J} \} \) then we may write \( (\Delta, \bar{J}) \) instead of \( \Lambda \)

(b) if \( \Delta = \{ \varphi(x, \bar{y}) \} \) we may write \( \varphi(x, \bar{y}) \) instead of \( \Delta \)

(c) if \( A \subseteq M \) and

\[
\bar{J} = \{ \bar{a} : \bar{a} \text{ is from } A, \text{ and for some } \varphi(x, \bar{y}) \in \Delta, \ell g(\bar{a}) = \ell g(\bar{y}) \}
\]

we may write \( A \) instead of \( \bar{J} \)

(d) if \( |M| = A \) we may write \( M \) instead \( A \), and we may omit it if clear from the context.

3) Supposing \( \psi(x, \bar{y}) := \varphi(\bar{y}, \bar{x}) \), \( I \) a linear order, we say \( \langle \bar{a}_s : s \in I \rangle \) is weakly \( (\kappa, \varphi(x, \bar{y})) \)-skeleton like inside \( M \) for \( \bar{J} \) when: \( \varphi(x, \bar{y}) \) is asymmetric (at least in \( M \)) with vocabulary contained in \( \tau(M) \), \( \ell g(\bar{a}_s) = \ell g(\bar{x}) = \ell g(\bar{y}), \langle \bar{a}_s : s \in I \rangle \) is weakly \( \kappa \)-skeleton like inside \( M \) for \( \{ \varphi(x, \bar{y}), \psi(x, \bar{y}) \}, \bar{J} \) and for every \( s, t \in I \) we have:

\[
M \models \varphi[\bar{a}_s, \bar{a}_t] \text{ iff } I \models s \prec t.
\]

4) In (1), (3), if \( M \) is clear from the context then we may omit “inside \( M \)”. In part (3), if \( \bar{J} = \alpha|M|, \alpha = \ell g(\bar{x}) = \ell g(\bar{y}) \) then we may omit it.

Discussion 3.2. Note that Definition \( p^2 \) requires considerably more than “the \( \bar{a}_s \) are ordered by \( \varphi \)” and even than “the \( \bar{a}_s \) are order indiscernibles, ordered by \( \varphi \)”, but much less than “\( M = \text{EM}_\kappa(I, \Phi) \)”.

We may view Definition \( p^2 \) as follows. An EM models \( M_1 = M_1^I \) for a theory \( T \) is a model of some theory \( T_1 \supseteq T \) with Skolem functions, \( |T_1| = |T| + \aleph_0 \) such that for some linear order \( I \) and elements \( a_s \in M_1 \) we have:

\[
(*) \quad (a) \ M_1 \text{ is the Skolem hull of } \langle a_s : s \in I \rangle
\]

(b) the sequence \( \langle a_s : s \in I \rangle \) is an indiscernible sequence in \( M_1 \); we may call it “the skeleton”.

So the model of \( T \) we are interested in is \( M_I = M_1|\tau(T) \); it is natural to assume properties of \( I \) are reflected in properties of \( M_I \) and so of \( M = M_I|\tau(M) \). The motivation in the original work \( [EhMo56] \) was understanding the automorphism group of \( M \); the automorphism group of \( I \) is naturally embedded into the automorphism group of \( M_I \) hence of \( M \). Anyhow here we are interested in getting \( 2^\lambda \) pairwise non-isomorphic models of cardinality \( \lambda \).

So naturally we consider:

\(^2\)The simplest example is: \( \Lambda \) the set of first order formulas with parameters from \( M \).
(c) fixing a formula \( \varphi(x, y) \) and pairs \((M, \langle a_s : s \in I \rangle)\) as above such that 
\[ M \models \varphi[a_s, a_t] \text{ iff } s < t \]

(d) a family \( \langle I_\alpha : \alpha < 2^\lambda \rangle \) of \( I \)'s of cardinality \( \lambda \), pairwise very different.

Furthermore, we would like not to restrict our models to such specific ones. So we look for a definition of “the sequence \( \langle a_s : s \in I \rangle \) of elements of \( M \) is in some sense like the situation is (b) above”. This is the motivation behind Definition 3.3 above and, in fact, (a) + (b) gives an example of it as proved in 3.3 below. Ideally in \( M_I \) we can reconstruct \( I \) in some sense, i.e. \( I/ \cong \). While very nice it seemed too much to hope for. So we may try to use “the \( I_\alpha \)'s are pairwise very different” but, even better, we shall define an invariant \( \text{inv}(I) \) of \( I \) and reconstruct it to a large extent.

So we may hope to replace “from \( M_I/ \cong \) we can define \( I/ \cong \)” by “from \( M_I/ \cong \) we can define \( \text{inv}(I) \)” We shall actually arrive to something very close to it: if we are given a model \( M \) of cardinality \( \lambda \) then there are at most \( \lambda \) invariant \( i \) such that

\[ \text{for some linear order } I \text{ and } a_s \in M \text{ for } s \in I \text{ such that the pair } (M, \langle a_s : s \in I \rangle) \text{ as above (for our fix } \varphi(x, y) \text{) satisfying } \text{inv}(I) = i. \]

Now if the set \( \{ \text{inv}(I) : I \text{ a linear order of cardinality } \lambda \} \) has cardinality \( \leq \lambda \) all this gives nothing, but if this set has cardinality \( 2^\lambda \) we are done. Note that actually we use \( \varphi(x_n, y_n), a_s \in^* M \) for some \( n \).

**Claim 3.3.**

1) Assume \( \Phi \) is an almost \( \mathcal{L} \)-nice template proper for linear orders (see Definition 2.8). Then for any linear order \( I \), the sequence \( (a_t : t \in I) \) is \( \mathbb{N}_0 \)-skeleton like for \( \mathcal{L} \) inside \( \text{EM}(I, \Phi) \); in fact, \( \mathcal{L}(\tau_\Phi) \) may be any set of formulas in the vocabulary \( \tau_\Phi \), e.g. \( \mathcal{L}(\tau_\Phi) \), first order logic for \( \tau_\Phi \).

2) In part (1), if \( I \) is \( \mathbb{N}_0 \)-homogeneous (i.e., for any \( n < \omega \) and \( t_0 < t_1 \cdots < t_n \), \( s_0 < t_1 \cdots < t_{s_0-1} \), there is an automorphism of \( I \) mapping \( t_k \) to \( s_k \) for \( k < n \)), then we can omit “almost \( \mathcal{L} \)-nice”.

**Proof.**

1) Let \( \varphi = \varphi(x, y) \in \mathcal{L}(\tau_\Phi), b \in \ell^g(\Phi)M, \) so for some finite sequence \( \bar{t} \) from \( I \) and a sequence \( \bar{\sigma} \) of \( \tau_\Phi \)-terms we have \( b = \bar{\sigma}(\bar{t}) \). So if \( s_1, s_2 \) realize the same quantifier free type over \( \bar{t} \) in \( I \), by indiscernibility (i.e., almost \( \mathcal{L} \)-niceness) then \( \text{EM}(I, \Phi) = \{ \varphi[a_{s_1}, b] = \varphi[a_{s_2}, b] \} \). So \( \text{rang}(I) \) is as required.

2) Should be clear.  

**Remark 3.4.**

1) Note that part \( \text{p8} \) (1) says that being skeleton-like really is a property of the skeleton of \( \text{EM} \)-models.

2) Note that \( \text{p8} \) (1) apply to \( \text{EM}_\tau(I, \Phi) \) whenever \( \tau \subseteq \tau_\Phi \).

We now will proceed to assign invariants to linear orders. We prove that there are enough linear orders with well defined pairwise distinct invariants. This is related to (but does not rely on) proofs from the Appendix to [Sh:c], where different terminology was employed. Speaking very roughly, we discussed there only \( \text{inv}^\omega_\kappa \) where \( \kappa = \mathbb{N}_0 \). The assertion in the appendix of [Sh:c] that two linear orders are contradictory corresponds to the assertion here that the invariants are defined and different.

**Notation 3.5.** In the following, for any regular cardinal \( \mu > \mathbb{N}_0, \mathcal{P}_\mu \) denotes the filter on \( \mu \) generated by the closed unbounded sets.

2) If \( D \) is a filter on \( \mu \) and \( X \subseteq \mu \) intersects each member of \( D \), then \( D + X \) denotes the filter generated by \( D \cup \{ X \} \).
2A) Similarly $D + \mathcal{A}$ for $\mathcal{A} \subseteq \mathcal{P}(\mu)$.

3) For a linear order $I = (I, <_I)$ the cofinality $\text{cf}(I)$ of $I$ is

$$\text{Min}\{|J| : J \subseteq I \text{ and } (\forall s \in I)(\exists t \in J)I | s < t\}.$$ 

4) $I^*$ is the inverse linear order and $\text{cf}^*(I)$ is the cofinality of $I^*$ sometimes called the coinitiality of $I$.

5) For a linear order $I$ and a cardinal $\kappa$, we define a filter on the regular cardinal $\text{cf}(I)$

$$\mathcal{D}(\kappa, I) := \mathcal{D}_{\text{cf}(I)} + \{\delta < \text{cf}(I) : \kappa \leq \text{cf}(\delta)\}.$$ 

6) For a filter $D$ on $\lambda$ (here mainly $\lambda = \text{cf}(I)$), two functions $f$ and $g$ from $\lambda$ to some set $X$, are equivalent mod $D$ when 

$$\{\alpha : f(\alpha) = g(\alpha)\} \in D.$$ 

7) We write $f/D$ for the equivalence class of $f$ for this equivalence relation when $f : \lambda \to X$ but we allow $f(\alpha)$ to be undefined for some $\alpha$’s as long as $\{\alpha < \lambda : f(\alpha)\}$ well defined.

**Definition 3.6.**

1) For a regular cardinal $\kappa$ (for example $\aleph_0$) and an ordinal $\alpha$ we define the invariant $\text{inv}_\alpha^\kappa(I)$ for linear orders $I$ (sometimes undefined), by induction on $\alpha$, by cases:

**Case 1**: $\alpha = 0$, $\text{inv}_0^\kappa(I)$ is the cofinality of $I$ if $\text{cf}(I) \geq \kappa$, and is undefined otherwise.

**Case 2**: $\alpha = \beta + 1$.

Let $I = \bigcup_{i<\text{cf}(I)} I_i$, where $I_i$ is increasing and continuous with $i$ and $I_i$ is a proper initial segment of $I$. For $\delta < \text{cf}(I)$ let $J_\delta = (I \setminus I_\delta)^*$ (recalling $X^*$ denotes the inverse order of $X$, recalling (3.5.4)).

If $\text{cf}(I) > \kappa$ and for some club $C$ of $\text{cf}(I)$:

$$(\ast) [\delta \in C \text{ and } \text{cf}(\delta) \geq \kappa] \Rightarrow \text{inv}_\alpha^\kappa(J_\delta) \text{ is well defined,}$$

then we let

$$\text{inv}_\alpha^\kappa(I) = \langle \text{inv}_\beta^\kappa(J_\delta) : \beta < \kappa, \delta < \text{cf}(I)\rangle / \mathcal{D}(\kappa, I).$$

Otherwise (i.e., there is no such $C'$ or $\text{cf}(I) \leq \kappa$) $\text{inv}_\alpha^\kappa(I)$ is not defined.

**Case 3**: $\alpha$ is limit

$$\text{inv}_\alpha^\kappa(I) = \langle \text{inv}_\beta^\kappa(I) : \beta < \alpha\rangle.$$ 

2) If $d = \text{inv}_d^\kappa(I)$ then “the cofinality of $d$” means $\text{cf}(I)$, clearly well defined.

**Remark 3.7.**

1) Really just $\alpha = 0, 1, 2$ are used. For regular $\lambda$, $\alpha = 1$ suffices, but for singular $\lambda$, $\alpha = 2$ is used (see (3.11). In [Sh:12] all the $\alpha$’s were used as Solovay’s theorem was not used.

2) The following lemma will be helpful as we will try to deal with cases of $\text{inv}$ inside models and try to prove that it is quite independent of a (relevant) choice of representatives.
Observation 3.8. 1) If $\beta \leq \alpha$ and $\text{inv}_\alpha^\beta(I) = \text{inv}_\alpha^\beta(J)$, and both are well defined then $\text{inv}_\alpha^\beta(I), \text{inv}_\alpha^\beta(J)$ are well defined and equal.

2) If $I, J$ are linear orders, $\text{inv}_\alpha^\beta(I)$ is well defined, $E$ is a convex equivalence relation on $J$, $f : J \rightarrow I$ preserves $\leq$, and $(f(x) = f(y)) \equiv (xEy)$, then $\text{inv}_\alpha^\beta(J)$ is well defined and $\text{inv}_\alpha^\beta(I) = \text{inv}_\alpha^\beta(J)$.

3) Assume that $\psi(x, y) = \varphi(y, x)$ and $\varphi(x, y) \in \{\varphi(x, y), \neg \varphi(x, y), \psi(x, y), \neg \psi(x, y)\}$ for $\ell = 1, 2$. Then $\langle \bar{a}_s : s \in I \rangle$ is weakly $(\kappa, \varphi_1(x, y))$-skeleton like in $M$ if and only if $\langle \bar{a}_s : s \in I \rangle$ is weakly $(\kappa, \varphi_2(x, y))$-skeleton like in $M$; also (by the asymmetry assumption) in $M$ we have $\varphi(x, y) \vdash \neg \psi(x, y)$ and $\psi(x, y) \vdash \neg \varphi(x, y)$.

Remark 3.9. 1) To understand the aim of \ref{3.10} below, think we may be considering $\langle \bar{a}_s : s \in I \rangle, \langle \bar{b}_t : t \in J \rangle$ such that for some linear order $U$, and $\langle \bar{c}_u : u \in U \rangle$ we have $\bar{c}_u \in lg(x)M$ and $\langle \bar{a}_s : s \in I \rangle \cdot \bar{c}_u : u \in U \rangle$ and $\langle \bar{b}_t : t \in J \rangle \cdot \bar{c}_u : u \in U \rangle$ are both weakly $(\kappa, \varphi(x, y))$-skeleton like in $M$ and $\text{cf}(U^+) \geq \kappa$.

2) We can omit assumption (c) in \ref{3.10}, so the conclusion will tell us that if one of $\text{inv}_\alpha^\beta(I)$, $\text{inv}_\alpha^\beta(J)$ is well defined then both are, but presently there is no real gain.

3) In \ref{3.10}(2), we cannot replace the assumption “$\text{inv}_\alpha^\beta(I)$ is well defined” by “$\text{inv}_\alpha^\beta(J)$ is well defined”.

Lemma 3.10. Suppose that $\kappa$ is a regular cardinal, $I, J$ are linear orders, and $\bar{a}_s$ (for $s \in I$), $\bar{b}_t$ (for $t \in J$) are from $M$, and $\varphi(\bar{x}, \bar{y})$ is a $\tau(M)$-formula $\kappa > lg(\bar{x}) \equiv \ell g(\bar{y}) \equiv \ell g(\bar{a}_s) \equiv \ell g(\bar{b}_t)$, and $\psi(\bar{x}, \bar{y}) \equiv \varphi(\bar{y}, \bar{x})$.

Assume:

(a) (\alpha) \quad for every $s \in I$ for every large enough $t \in J, M \models \varphi[\bar{a}_s, \bar{b}_t],$

(b) \quad for every $t \in J$ for every large enough $s \in I, M \models \neg \varphi[\bar{a}_s, \bar{b}_t],$

(c) \quad $\langle \bar{a}_s : s \in I \rangle$ is weakly $(\kappa, \varphi(\bar{x}, \bar{y}))$-skeleton like inside $M$,

(d) \quad $\langle \bar{b}_t : t \in J \rangle$ is weakly $(\kappa, \varphi(\bar{x}, \bar{y}))$-skeleton like inside $M$,

Then $\text{inv}_\alpha^\beta(I) = \text{inv}_\alpha^\beta(J)$.

Proof. By induction on $\alpha$.

First Case: $\alpha = 0$

Assume not, so $\text{inv}_0^\beta(I) \neq \text{inv}_0^\beta(J)$. Then by Definition \ref{3.10} we have $\text{cf}(I), \text{cf}(J)$ are distinct (and $\geq \kappa$). By symmetry, without loss of generality $\text{cf}(I) > \text{cf}(J)$, so $\text{cf}(I) > \kappa$.

Let $\langle t_\zeta : \zeta < \text{cf}(I) \rangle$ be increasing unbounded in $J$. For each $\zeta < \text{cf}(J)$ (by clause (a)/(\beta) of \ref{3.10}) and $\zeta \in I$ there is $s_\zeta \in I$ such that:

\[ s_\zeta \leq s \in I \Rightarrow M \models \neg \varphi[\bar{a}_s, \bar{b}_t]. \]

As $\text{cf}(I) > \text{cf}(J)$ there is $s \in I$ such that $\bigwedge_{\zeta < \text{cf}(I)} s_\zeta < s$. Now, the set

\[ \{ t \in J : M \models \neg \varphi[\bar{a}_s, \bar{b}_t] \} \]

includes each $t_\zeta$ (as $s_\zeta < s \in I$), and hence it is unbounded in $J$, contradicting clause (a)/(\alpha) of \ref{3.10}.

Second Case: $\alpha = \beta + 1$
By the first case and Definition 3.11 we have \( \text{cf}(I) = \text{cf}(J) \geq \kappa \). Let \( \lambda = \text{cf}(I) = \text{cf}(J) \); let

\[
I = \bigcup_{i < \lambda} I_i,
\]

where \( I_i \) is increasing continuous in \( i \), \( I_i \) a proper initial segment of \( I \) and \( [i \neq j \Rightarrow I_i \neq I_j] \).

Similarly let

\[
J = \bigcup_{i < \lambda} J_i.
\]

Choose \( s_i \in I_{i+1} \setminus I_i \) and \( t_i \in J_{i+1} \setminus J_i \). By assumption (a), for every \( i < \lambda \) there is \( j_i < \lambda \) such that:

1. \( (\alpha)' \) if \( t \in J \setminus J_{j_i} \), then \( M \models \varphi[\bar{a}_{s_i}, \bar{b}_j] \),
2. \( (\beta)' \) if \( s \in I \setminus I_{j_i} \), then \( M \models \neg \varphi[\bar{a}_{s_i}, \bar{b}_j] \).

Let

\[
\mathcal{C} = \{ \delta < \lambda : \delta \text{ is a limit ordinal and } i < \delta \Rightarrow j_i < \delta \};
\]

it is a club of \( \lambda \). For \( \delta \in \mathcal{C} \) let \( I^\delta = (I \setminus I_{j_i})^\ast \) and let \( J^\delta = (J \setminus J_{j_i})^\ast \). By Definition 3.12 above it suffices to prove, for \( \delta \in \mathcal{C} \) satisfying \( \text{cf}(\delta) \geq \kappa \) and \( \text{inv}_\kappa^\delta(I^\delta) \), \( \text{inv}_\kappa^\delta(J^\delta) \) are defined, that:

\[
(\ast)_\delta \ \text{inv}_\kappa^\delta(I^\delta) = \text{inv}_\kappa^\delta(J^\delta).
\]

For this we use the induction hypothesis, but we have to check that the assumptions (a), (b), (c) hold for this case.

Now clause (c) is part of the assumption of \( (\ast)_\delta \), and clause (b) is inherited from the same property of \( \langle \bar{a}_s : s \in I \rangle , \langle \bar{b}_t : t \in J \rangle \); lastly clause (a) follows from \( (\alpha)' + (\beta)' \) above as \( \delta \in \mathcal{C} \). In detail, if \( t \in J^\delta \) then \( J \models \neg t_j < t \) for \( j < \delta \). Hence, for \( i < \delta \), \( M \models \varphi[\bar{a}_{s_i}, \bar{b}_j] \) (by clause (a) above). So by clause (b)(\beta) from the assumptions, for every large enough \( s \in I^\delta \) we have \( M \models \varphi[\bar{a}_s, \bar{b}_j] \), which means that \( \langle \bar{a}_s : s \in I^\delta \rangle , \langle \bar{a}_t : t \in J^\delta \rangle \) satisfy clause (a)(\alpha). Similarly clause (a)(\beta) holds.

Third Case: \( \alpha \) is limit

Immediate by Definition 3.17. \( \square \)

**Lemma 3.11.**

1) If \( \lambda, \kappa \) are regular, \( \lambda > \kappa \), then there are \( 2^\lambda \) linear orders \( I_\alpha \) (for \( \alpha < 2^\lambda \)), each of cardinality \( \lambda \), with pairwise distinct \( \text{inv}_\kappa^\lambda(I_\alpha) \) (for \( \alpha < 2^\lambda \)), each well defined.

2) If \( \lambda > \kappa \), \( \kappa \) is regular, then there are linear orders \( I_\alpha \) (for \( \alpha < 2^\lambda \)), each of cardinality \( \lambda \) with pairwise distinct \( \text{inv}_\kappa^\lambda(I_\alpha) \) (for \( \alpha < 2^\lambda \)), each well defined.

3) If in (2) we have \( \lambda > \theta = \text{cf}(\theta) > \kappa \), then we can have \( \text{cf}(I_\alpha) = \theta \) if we use \( \text{inv}_\kappa^\lambda \). Similarly, if in part (1) we have \( \lambda > \theta = \text{cf}(\theta) > \kappa \), then we can have \( \text{cf}(I_\alpha) = \theta \) if we use \( \text{inv}_\kappa^\lambda \); of course can use \( \text{inv}_\kappa^\lambda \) for \( \alpha \geq 2 \) (similarly elsewhere).

**Remark 3.12.** The construction of the linear orders is “hinted at” by the proof above, and by the properties of stationary sets. Alternatively see the inductive construction in [Sh:c, Appendix 3.7.3.8], or see [Sh:12] where \( \text{inv}_\kappa^\lambda(1), \alpha < \lambda^+ \), \( \lambda = |I| \) are used.
Proof. 1) So $\lambda > \kappa$ are regular. The set $S = \{ \delta < \lambda : \text{cf}(\delta) = \kappa \}$ is stationary and hence we can find a partition $\langle S_\epsilon : \epsilon < \lambda \rangle$ of $S$ into pairwise disjoint stationary subsets (well known, see Solovay’s theorem). For $u \subseteq \lambda$ we define $I_u$ as the set

$$\{ (\alpha, \beta) : \alpha < \lambda \text{ and } \alpha \in \bigcup_{\epsilon \in u} S_\epsilon \Rightarrow \beta < \kappa^+ \text{ and } \alpha \in \lambda \setminus \bigcup_{\epsilon \in u} S_\epsilon \Rightarrow \beta < \kappa \}$$

linearly ordered by:

$$(*) \quad (\alpha_1, \beta_1) <_{I} (\alpha_2, \beta_2) \text{ if } \alpha_1 < \alpha_2 \text{ or } (\alpha_1 = \alpha_2 \text{ and } \beta_1 > \beta_2).$$

(Yes! we mean $\beta_1 > \beta_2$ not $\beta_1 < \beta_2$). By the proof of 3.10 above clearly $\langle I_u : u \subseteq \lambda \rangle$ is as required.

2) So we have $\lambda > \kappa$, $\kappa = \text{cf}(\kappa)$.

Let $\lambda = \sum_{i < \text{cf}(\lambda)} \lambda_i$, $\lambda_i$ increasing continuous $> \kappa$, let $\theta = \text{cf}(\lambda) + \kappa^+$, or just $\kappa^+$ and $\text{cf}(\lambda) \leq \theta = \text{cf}(\theta) \leq \lambda$. Recall $2^\lambda = \lambda^{\sum_{i < \text{cf}(\lambda)}} = \prod_{i < \text{cf}(\lambda)} 2^{\lambda_i}$, this motivates the following.

Let $h : \theta \rightarrow \text{cf}(\lambda)$ be such that for any $i < \text{cf}(\lambda)$ the set $\{ \delta < \theta : \text{cf}(\delta) = \kappa \text{ and } h(\delta) = i \}$ is stationary.

For each $i$, let $\langle I_{i,\epsilon} : \epsilon < 2^{\lambda_i} \rangle$ be as in the proof of (1) for $\lambda_i^+$. For any $\nu \in \prod_{i < \text{cf}(\lambda)} 2^{\lambda_i}$ let $J_{i,\nu} = \sum_{\alpha < \theta} J_{i,\alpha,\nu}$ with $J_{i,\alpha,\nu} \cong I_{i,\alpha} \cup (b(\alpha))$.

3) Let $\langle I_\epsilon : \epsilon < 2^\lambda \rangle$ be as guaranteed in part (2) (or part (1) if $\lambda$ is regular). For each $\epsilon < 2^\lambda$, let $J_\epsilon = \sum_{i < \theta} J_{i,\epsilon,i}$ where $J_{i,\epsilon,i} \cong I_\epsilon$; now the sequence $\langle I_\epsilon : \epsilon < 2^\lambda \rangle$ is as required. \( \square \)

Discussion 3.13. Instead considering $\bar{c} \in \partial M$ we may add a filter $D$ on $\partial$ and consider only $\bar{c}/D$, or even $\bar{c}/E_\mu$, $E_M$, a definable equivalence relation on $\partial M$.

§ 3B. Representing Invariants.

Now we would like essentially to attach the invariants of a linear order $I$ to a model $M$ which has a skeleton-like sequence indexed by $I$. In (a) (in Definition 3.14 below) we define what it means for a sequence indexed by $I$ to $(\kappa, \theta)$-represent the $(\varphi, \psi)$-type of $\bar{c}$ over $A$.

Definition 3.14. Let $A \subseteq M, \bar{c} \in M$ and $\varphi(\bar{x}, \bar{y})$ be an asymmetric formula with vocabulary contained in $\tau(M)$ and $\psi(\bar{x}, \bar{y}) = \varphi(\bar{y}, \bar{x})$.

(a) We say that $\langle \bar{a}_s : s \in I \rangle$ does $(\kappa, \theta)$-represents the tuple $(\bar{c}, A, M, \varphi(\bar{x}, \bar{y}))$ when $I$ is a linear order, $\text{cf}(I) \geq \kappa$ and for some linear order $J$ of cofinality $\theta \geq \kappa$ disjoint to $I$, there are $\bar{a}_t \in \varphi(\bar{x}, A)$ for $t \in J$, such that:

(i) for every large enough $t \in I$, $\bar{a}_t$ realizes $tp_{\varphi(x, y), \psi(x, y)}(\bar{c}, A, M)$, and

(ii) $\langle \bar{a}_s : s \in J+\langle I \rangle^* \rangle$ is weakly $(\kappa, \varphi(\bar{x}, \bar{y}))$-skeleton like inside $M$ (recalling $I^*$ denotes the inverse of $I$).

(b) We say that $(\bar{c}, A, M, \varphi(\bar{x}, \bar{y}))$ has a $(\kappa, \theta, \alpha)$-invariant when:
(i) if for $\ell = 1,2, \langle \bar{a}^\ell : s \in I_\ell \rangle$ does $(\kappa, \theta)$-represents $(\bar{c}, A, M, \varphi(\bar{x}, \bar{y}))$ and $\text{inv}^\alpha(I_\ell)$ are well defined for $\ell = 1,2$ then $\text{inv}^\alpha(I_1) = \text{inv}^\alpha(I_2)$.

(ii) some $(\bar{a}_s : s \in I)$ does $(\kappa, \theta)$-represent $(\bar{c}, A, M, \varphi(\bar{x}, \bar{y}))$ and $\text{inv}^\alpha(I)$ is well defined.

(γ) Let $\text{INV}^{\alpha, \theta}(c, A, M, \varphi(\bar{x}, \bar{y}))$ be $\text{inv}^\alpha(I)$ when $(\bar{c}, A, M, \varphi(\bar{x}, \bar{y}))$ has $(\kappa, \theta, \alpha)$-invariant and $(\bar{a}_s : s \in I)$ does $(\kappa, \theta)$-represent it. Similarly for “$\kappa$-represents” and $\text{INV}^{\alpha, \theta}(c, A, M, \varphi(\bar{x}, \bar{y}))$ (justified by Fact 3.21 below).

**Fact 3.15.** Suppose that for $\ell = 1,2$, the sequence $\langle a^\ell_s : s \in I_\ell \rangle$ does $(\kappa, \theta)$-represent $(\bar{c}, A, M, \varphi(\bar{x}, \bar{y}))$. Then $\theta_1 = \theta_2$.

**Proof.** So let for $\ell = 1,2$ the sequence $\langle a^\ell_s : s \in J_\ell \rangle$ witness that $\langle a^\ell_s : s \in I_\ell \rangle$ does $(\kappa, \theta)$-represent $(\bar{c}, A, M, \varphi(\bar{x}, \bar{y}))$, i.e., they are as in (α) of Definition 3.24. Assume toward contradiction that $\theta_1 \neq \theta_2$ and by symmetry without loss of generality $\theta_1 < \theta_2$. Let $(s_\ell(\alpha) : \alpha < \theta_1)$ be an increasing unbounded sequence of members of $J_\ell$ for $\ell = 1,2$. So for each $\alpha < \theta_1$ we have

$$t \in I_1 \Rightarrow M \models \varphi[\bar{a}^1_{s_1(\alpha)}, \bar{a}^1_2]$$

and hence by clause (i) of (α) of Definition 3.24 we have $M \models \varphi[\bar{a}^1_{s_1(\alpha)}, \bar{c}]$ recalling $\bar{a}^1_{s_1(\alpha)} \subseteq A$, so for every large enough $t \in I_2, M \models \varphi[\bar{a}^1_{s_1(\alpha)}, \bar{a}^2_2]$. But $(a^2_\ell : t \in J_2 + (I_2)^\alpha)$ is weakly $(\kappa, \varphi(\bar{x}, \bar{y}))$-skeleton like inside $M$, hence for some $\beta_\alpha < \theta_2$ we have

$$s_2(\beta_\alpha) \leq t \in J_2 \Rightarrow M \models \varphi[\bar{a}^1_{s_1(\alpha)}, \bar{a}^2_2]$$

and so $\beta(\ast) = \sup(\beta_\alpha + 1 : \alpha < \theta_1) < \theta_2$ (as $\theta_1 < \theta_2 = \text{cf}(\theta_2)$). So $M \models \varphi[\bar{a}^1_{s_1(\alpha)}, \bar{a}^2_{s_2(\beta(\ast))}]$ for $\alpha < \theta_1$.

But $t \in I_2 \Rightarrow M \models \varphi[\bar{a}^2_1, \bar{a}^2_{s_2(\beta(\ast))}]$ and hence $M \models \varphi[\bar{a}^2_1, \bar{a}^2_{s_2(\beta)}]$. Therefore, for every large enough $t \in I_1$, $M \models \varphi[\bar{a}^1_1, \bar{a}^2_{s_2(\beta)}]$ and hence for every large enough $t \in J_1$, $M \models \varphi[\bar{a}^1_1, \bar{a}^2_{s_2(\beta)}]$. Hence this holds for $t \equiv s_1(\alpha)$, $\alpha$ large enough, a contradiction to the previous paragraph. See more in 3.21(2).
Definition 3.17. Let $\varphi(\bar{x}, \bar{y})$ be an asymmetric formula with vocabulary $\subseteq \tau(M)$ (where $\ell g(\bar{x}) = \ell g(\bar{y})$ is finite), and let $M$ be a model of cardinality $\lambda$, $\lambda > \kappa$, $\kappa$ regular, $\alpha$ be an ordinal.

0) A representation of the model $M$ is an increasing continuous sequence $\bar{M} = \langle M_i : i < \text{cf}(\lambda) \rangle$ such that $\|M_i\| < \lambda$, and $M = \bigcup_{i<\text{cf}(\lambda)} M_i$.

0A) Similarly for sets.

1) For a regular cardinal $\lambda$:

$$\text{INV}^\alpha_{\kappa}(M, \varphi(\bar{x}, \bar{y})) = \{d_i : i < \theta\}/\mathcal{D}_{\theta, \kappa} :$$

for every representation $\langle A_i : i < \lambda \rangle$ of $|M|$, there are $\delta < \lambda$ and $\bar{c} \in M$ (of course, $\ell g(\bar{c}) = \ell g(\bar{x})$) such that $\text{cf}(\delta) \geq \kappa$ and $d_i = \text{INV}^\alpha_{\kappa}(\bar{c}, A_i, M, \varphi(\bar{x}, \bar{y}))$, (so in particular the latter is well defined).

2) For regular cardinals $\theta > \kappa$ such that $\lambda > \text{cf}(\lambda) = \theta$ we let

$$\mathcal{D}_{\theta, \kappa} = \mathcal{D}_{\theta} + \{\delta < \theta : \text{cf}(\delta) \geq \kappa\}$$

and

$$\text{INI}^\alpha_{\kappa, \theta}(M, \varphi(\bar{x}, \bar{y})) = \{\langle d_i : i < \theta \rangle/\mathcal{D}_{\theta, \kappa} :$$

for every representation $\langle A_i : i < \theta \rangle$ of $|M|$, there is $S \subseteq \mathcal{D}_{\theta, \kappa}$ satisfying:

for every $\delta \in S$ there is $\bar{c}_\delta \in M$ such that $d_\delta = \text{INV}^\alpha_{\kappa}(\bar{c}_\delta, A_\delta, M, \varphi(\bar{x}, \bar{y}))$ so is well defined and the cofinality of $d_\delta$ is $> |A_\delta|$.

3) For regular cardinals $\kappa > \theta$, $\lambda > \theta > \kappa + \text{cf}(\lambda)$ and a function $h$ with domain a stationary subset of $\{\delta < \theta : \text{cf}(\delta) \geq \kappa\}$ and range a set of regular cardinals $< \lambda$, we let

$$\mathcal{D}_{\theta, h} = \mathcal{D}_{\theta} + \{\delta < \theta : h(\delta) \geq \mu\} \text{ (hence } \delta \in \text{Dom}(h)) : \mu < \lambda\},$$

and assuming that $\mathcal{D}_{h, \kappa}$ is a proper filter we let:

$$\text{INV}^\alpha_{\kappa, h}(M, \varphi(\bar{x}, \bar{y})) = \{\langle d_i : i < \theta \rangle/\mathcal{D}_{\theta, h} :$$

for every representation $\langle A_i : i < \text{cf}(\lambda) \rangle$ of $|M|$, there are $\gamma < \text{cf}(\lambda)$ and $S \subseteq \mathcal{D}_{h, \kappa}$, $S \subseteq \text{Dom}(h)$, satisfying the following for each $\delta \in S$, if $h(\delta) > |A_\gamma|$ then for some $\bar{c}_\delta \in M$, we have $d_\delta = \text{INV}^\alpha_{\kappa}(\bar{c}_\delta, A_\gamma, M, \varphi(\bar{x}, \bar{y}))$ so is well defined and the cofinality of $d_\delta$ is $> |A_\gamma|$.

Remark 3.18. Of course, also in $\mathcal{D}_{\mathcal{D}_{\theta}}(1)$ we could have used $\langle d_i : i < \lambda \rangle/\mathcal{D}_{\theta}$ as the invariant.

Lemma 3.19. Suppose $\varphi(\bar{x}, \bar{y})$ is a formula in the vocabulary of $M$, $\ell g(\bar{x}) = \ell g(\bar{y}) < \omega$.

1) If $\lambda > \aleph_0$ is regular, $M$ a model of cardinality $\lambda$, $\kappa$ regular $< \lambda$, then $\text{INV}^\alpha_{\kappa}(M, \varphi(\bar{x}, \bar{y}))$ has cardinality $\leq \lambda$.

2) If $\lambda$ is singular, $\theta = \text{cf}(\lambda) > \kappa$, then $\text{INV}^\alpha_{\kappa, \theta}(M, \varphi(\bar{x}, \bar{y}))$ almost has cardinality $\leq \lambda$, which means: there are no $d_\zeta^i$ (for $i < \theta$, $\zeta < \lambda^+$) such that:
(i) for $\zeta < \lambda^+$, $(d^\zeta_i : i < \theta)/\mathcal{D}_{\theta, \kappa} \in \text{INV}^\alpha_{\kappa, \theta}(M, \varphi(x, y))$,

(ii) for $i < \theta, \zeta < \xi < \lambda^+$, we have $d^\zeta_i \neq d^\xi_i$.

3) If $\lambda$ is singular, $\theta, \kappa$ are regular, $\kappa + \text{cf}(\lambda) < \theta < \lambda$, $h$ is a function from some stationary subset of $\{i < \theta : \text{cf}(i) \geq \kappa\}$ into 

$$\{\mu < \lambda : \mu \text{ is a regular cardinal}\}$$

such that $\mathcal{D}_{\theta, h}$ is a proper filter, then $\text{INV}^\alpha_{\kappa, \theta}(M, \varphi(x, y))$ almost has cardinality $\leq \lambda$, which means: there are no $d^\zeta_i (i < \theta, \zeta < \lambda^+)$ such that:

(i) for $\zeta < \lambda^+$, $(d^\zeta_i : i < \theta)/\mathcal{D}_{\theta, h} \in \text{INV}^\alpha_{\kappa, \theta}(M, \varphi(x, y))$,

(ii) for $i < \theta, \zeta < \xi < \lambda^+$, we have $d^\zeta_i \neq d^\xi_i$.

Proof. Straightforward. $\square_{17}$

$3C$ § 3(C). Harder Results.

We now show that (for example for the case $\lambda$ regular) if $|I| \leq \lambda$ and $\text{inv}^\alpha_{\kappa}(I)$ is well defined then there is a linear order $J$ such that: if a model $M$ has a weakly $(\kappa, \varphi)$-skeleton like sequence inside $M$ of order-type $J$ then $\text{inv}^\alpha_{\kappa}(J) \in \text{INV}^\alpha_{\kappa}(M, \varphi)$.

Again, the proof splits into three cases depending on the cofinality of $\lambda$. The following result provides a detail needed for the proof.

Claim 3.20. Suppose that $\kappa$ is a regular cardinal and $(\bar{a}_t : t \in J)$ is a weakly $(\kappa, \varphi)$-skeleton like inside $M$ and $I \subseteq J$. If for each $s \in J \setminus I$ either $\{t \in J : t < s\}$ or the inverse order on $\{t \in J : t > s\}$ has cofinality less than $\kappa$ (for example 1) then $(\bar{a}_t : t \in I)$ is weakly $(\kappa, \varphi)$-skeleton like for $M$.

Proof. As usual let $\psi(x, y) := \varphi(y, x)$. We must show that for every $\bar{a} \in \mathcal{B}(\bar{x})M$ there is an $I_0 \subseteq I$ with $|I_0| < \kappa$ such that: if $s, t \in I$ and $\text{tp}_{qf}(s, I_0, I) = \text{tp}_{qf}(t, I_0, I)$ then

$$M \models \varphi(\bar{a}_s, \bar{a}) \equiv \varphi(\bar{a}_t, \bar{a}) \quad \text{and} \quad M \models \psi(\bar{a}_s, \bar{a}) \equiv \psi(\bar{a}_t, \bar{a}).$$

We know that there is such a set $J_0$ for $J$ and $\bar{a}$ and for each $s \in J_0$ choose a set $X_s$ of $< \kappa$ elements of $I$ such that $X_s$ tends to $s$, i.e., to the cut that $s$ induces in $I$ (either from above or below). (So if $s \in I$, $X_s = \{s\}$; otherwise use the assumption.) Let $I_0 = \bigcup_{s \in J_0} X_s$; as $\kappa$ is regular, $|X_s| < \kappa$ for $s \in J_0$ and $|I_0| < \kappa$ clearly $I_0$ has cardinality $< \kappa$; also trivially $J_0 \subseteq I$.

Now it is easy to see that if $t_1$ and $t_2 \in I$ have the same quantifier free type over $I_0$, then they have the same quantifier free type over $J_0$, and the claim follows. $\square_{20}$

Also the following will be used in proving $5$: 22:

Fact 3.21. 1) Suppose $(\bar{a}_s : s \in J + J^*)$ is weakly $(\kappa, \varphi(\bar{x}, \bar{y}))$-skeleton like inside $M$ and both $J$ and $I$ have cofinality $\geq \kappa$. Then for every $\bar{b} \in M$ there exist $s_0 \in J$ and $s_1 \in J^*$ such that:
3) Let $i < \theta$ increasing continuous. Suppose that for large $\lambda$
2) Let $\ell \leq \lambda$ for some linear order $\ell$
and $c$ realize the same $\mathcal{I}$.
2) Suppose that, for $\ell \leq \lambda$, such that they are both well defined.

Proof. 1) Easy.
2) As we can replace $I^\ell$ by any end segment, without loss of generality

$(\ast)$ for $\ell = 1, 2$ for every $t \in I^\ell$, $\bar{a}_t$ realizes $tp_{(\varphi(x,y), \psi(x,y))}(\bar{c}, A, M)$.

We shall use Lemma 3.21 (with $I^1, I^2$ here standing for $I, J$ there and $\psi$ for $\varphi$).
Conditions (b), (c) from 3.21 are trivially, for (b) using 3.22. By similar arguments in condition (a) it is enough to prove clause (a).

Let us prove (a) from 3.21. So suppose it fails, i.e., $s \in I^1$ but for arbitrarily large $t \in I^2$, $M \models \neg \varphi[\bar{a}_t^2, \bar{a}_t^2]$. Since $\langle \bar{a}_t^2 : t \in J^2 + (I^2)^{\ast} \rangle$ is weakly $(\kappa, \varphi)$-skeleton like inside $M$, the preceding
Fact 3.21(1) yields that for arbitrarily large $t \in J^2$, $M \models \neg \varphi[\bar{a}_t^2, \bar{a}_t^2]$. Since $\bar{a}_t$ and $\bar{c}$ realize the same $\{\varphi, \psi\}$-type over $A_t$ (see definition 3.1(4) (a) and $(\ast)$ above), and as $\bar{a}_t \subseteq A_t$ for $t \in J^2$, this implies $M \models \neg \varphi[\bar{c}, \bar{a}_t^2]$, so this holds for arbitrarily large $t \in J^2$. Choose such $t_0 \in J^2$, this quickly contradicts the choice of $J^2$ and $I^2$. For, it implies that for every $t \in I^2$ (as $\bar{c}, \bar{a}_t^2$ realize the same $\{\varphi, \psi\}$-type over $A_t$) we have

$$M \models \neg \varphi[\bar{a}_t^2, \bar{a}_t^2],$$

which is impossible as $\langle \bar{a}_s : s \in J^2 + (I^2)^{\ast} \rangle$ is weakly $(\kappa, \varphi)$-skeleton like (see Definition 3.1(3) the last phrase).

\begin{lemma}
Assume $\ell_0(\bar{x}) = \ell_0(\bar{y}) < \aleph_0$ and $\varphi = \varphi(\bar{x}, \bar{y})$.
1) Let $\lambda > \aleph_0$ be regular. If $I$ is a linear order of cardinality $\leq \lambda$, and $inv^\alpha(I)$ is well defined, then for some linear order $J$ of cardinality $\lambda$ the following holds:

$$(\ast) \text{ if } M \text{ is a model of cardinality } \lambda, \bar{a}_s \in \ell(\bar{x}), \langle \bar{a}_s : s \in J \rangle \text{ is weakly } (\kappa, \varphi(\bar{x}, \bar{y}))\text{-skeleton like inside } M \text{ (hence } \varphi(\bar{x}, \bar{y}) \text{ is asymmetric)}, \text{ then } inv^\alpha(I) \in INV^\alpha(M, \varphi(\bar{x}, \bar{y})).$$

2) Let $\lambda$ be singular, $\theta = cf(\lambda) > \kappa$, $\lambda = \sum_{i < \theta} \lambda_i$, where the sequence $\langle \lambda_i : i < \theta \rangle$ is increasing continuous. Suppose that for $i < \theta$, $I_i$ is a linear order of cofinality $> \lambda_i$ and cardinality $\leq \lambda$ such that $inv^\alpha(I_i)$ is well defined. Then for some linear order $J$ of cardinality $\lambda$ the following holds:

$$(***) \text{ if } M \text{ is a model of cardinality } \lambda, \bar{a}_s \in \ell(\bar{x}) M \text{ for } s \in J, \langle \bar{a}_s : s \in J \rangle \text{ is weakly } (\kappa, \varphi(\bar{x}, \bar{y}))\text{-skeleton inside } M, \text{ (so } \varphi(\bar{x}, \bar{y}) \text{ asymmetric), then } inv^\alpha(I) \in INV^\alpha(M, \varphi(\bar{x}, \bar{y})).$$

3) Let $\lambda$ be singular, $\theta, \kappa$ be regular, $\lambda > \theta > (cf(\lambda) + \kappa)$, $\lambda = \sum_{i < cf(\lambda)} \lambda_i$, $\lambda_i$ increasing continuous. If, for $i < \theta$, $I_i$ is a linear order such that $inv^\alpha(I_i)$ is well defined, then for some linear order $J$ of cardinality $\lambda$ the following holds:
(* * *) if $M$ is a model of cardinality $\lambda$, $\bar{a}_s \in \ell g(\nu) M$ for $s \in J$, $\langle \bar{a}_s : s \in J \rangle$ is weakly $(\kappa, \varphi(x, y))$-skeleton like inside $M$, (so $\varphi(x, y)$ asymmetric), $h$ is a function from a stationary subset of $\{ \delta < \theta : \text{cf}(\delta) \geq \kappa \}$ with range a set of regular cardinals $< \lambda$ but $> \theta$ such that \(\text{cf}(I_s) \geq h(i)\) and $\mathcal{D}_{\theta, h}$ is a proper filter then \(\langle \text{inv}_{\kappa}^{\alpha}(I_i) : i < \theta \rangle / \mathcal{D}_{\theta, h} \) belongs to $\text{INV}_{\kappa, h}^\alpha (M, \varphi(x, y))$.

Proof. 1) We must choose a linear order $J$ of cardinality $\lambda$ such that: if $J$ indexes a weakly $(\kappa, \varphi(x, y))$-skeleton like sequence inside $M$, a model of cardinality $\lambda$, then

$$\text{inv}_{\kappa}^{\alpha}(I) \in \text{INV}_{\kappa}^{\alpha} (M, \varphi(x, y)).$$

For this, for any continuous increasing decomposition $A$ of $|M|$, we must find a sequence $\bar{c} \in M$ and an ordinal $\delta < \lambda$ of cofinality $\kappa$ with

$$\text{INV}_{\kappa}^{\alpha} (\bar{c}, A, M, \varphi(x, y)) = \text{inv}_{\kappa}^{\alpha}(I).$$

To obtain $\bar{c}$, we shall use a function from $\lambda$ to $J$. Let $\lambda_{\alpha}$ for $\alpha < \lambda$ be pairwise disjoint linear orders isomorphic to $I$.

Let $J = \sum_{\alpha < \lambda} I_{\alpha}$ (where $I^*$ means we use the inverse of $I$ as an ordered set).

Suppose $\langle \bar{a}_s : s \in J \rangle$ is weakly $(\kappa, \varphi(x, y))$-skeleton like inside $M$, (hence $\varphi(x, y)$ is asymmetric) and $M$ has cardinality $\lambda$. For $\alpha < \lambda$ let $s(\alpha) \in I_{\alpha}$ and let $\langle A_{\alpha} : \alpha < \lambda \rangle$ be an increasing continuous sequence such that $M = \{ A_{\alpha} : \alpha < \lambda \}$, $|A_{\alpha}| < \lambda$.

By the definition of weakly $(\kappa, \varphi(x, y))$-skeleton like (Definition \(\ell 24.1(1)\)), for every $\bar{a} \in \ell g(\nu) M$, here is a subset $J_{\alpha}$ of $J$ of cardinality $< \kappa$ such that: if $s, t \in J \setminus J_{\alpha}$ induces the same Dedekind cut on $J_{\alpha}$, then $M \models "\varphi[\bar{a}, \bar{a}] \equiv \varphi[\bar{a}, \bar{a}]"$ and $M \models \text{"}\varphi[\bar{a}, \bar{a}] \equiv \varphi[\bar{a}, \bar{a}]"$.

Since $\lambda$ is regular, for some closed unbounded subset $\mathcal{C}$ of $\lambda$, for every $\delta \in \mathcal{C}$ we have:

1. $(\ast)$ (i) $\bar{a}_{s(\alpha)} \in \ell g(\nu) (A_{\delta})$ for $\alpha < \delta$,
2. (ii) $J_{\delta} \subseteq \sum_{\beta < \delta} I_{\beta}^*$ for $\bar{a} \in \ell g(\nu) (A_{\delta})$.

So it is enough to prove that for any $\delta \in \mathcal{C}$ of cofinality $\kappa$ we have

$$\text{inv}_{\kappa}^{\alpha}(I) = \text{INV}_{\kappa}^{\alpha} (\bar{a}_{s(\delta)}, A_{\delta}, M, \varphi(x, y)).$$

Let $\mathcal{C} \subseteq \delta$ be closed unbound of order types $\text{cf}(\delta)$. Now we shall show that $\langle \bar{a}_s : s \in I_\delta \rangle$ does $\kappa$-represents $\langle \bar{a}_{s(\delta)} : A_{\delta}, M, \varphi(x, y) \rangle$: the required $\theta$ and $J$ in Definition \(\ell 24(\alpha)\) are $\text{cf}(\delta)$ and $\langle \bar{a}_{s(\beta)} : \beta \in \mathcal{C} \rangle$, and clause (i) of \(\ell 24(\alpha)\) holds by $(\ast)(ii)$ above and clause (ii) of \(\ell 24(\alpha)\) holds by claim \(\ell 240\) with $J, \{ s(\beta) : \beta \in \mathcal{C} \} \cup I_\delta^*$ here standing for $J, I$ there.

So (see Definition \(\ell 24(\gamma)\)) it is enough to show that $(\bar{a}_{s(\delta)}, A_{\delta}, M, \varphi(x, y))$ has a $(\kappa, \alpha)$-invariant. Now in Definition \(\ell 24(\beta)\), part (ii) is obvious by the above; so it remains to prove (i).

Let $\theta = \text{cf}(\delta)$. So assume that for $\ell = 1, 2$,

$$\langle \bar{a}_s^\ell : s \in I_\delta \rangle \text{ weakly } (\kappa, \theta)\text{-represents } (\bar{a}_{s(\delta)}, A_{\delta}, M, \varphi(x, y)).$$
Let $J'$, $\langle a'_i : t \in J' \rangle$ exemplify this (so each $a'_i$ belongs to $A_δ$) and let $J''_i = J' + (I'_i)^*$ and assume $\text{inv}^\alpha(J')$ are well defined. We have to prove that $\text{inv}^\alpha(I') = \text{inv}^\alpha(I'')$. This follows by 3.21(2) above.

2),3) Similar to the proof of part (1), using $J = \sum_{i \in \emptyset} (I_i)^*$ where $I_i \cong I$ are pairwise disjoint. So left to the reader (or see the proof of case (d) and formulation of case (e) in Theorem 3.29). □

Remark 3.23. 1) In the proof of 3.22, instead “$\theta = \text{cf}(\delta) = \kappa$” we can use $\theta = \text{cf}(\delta) \geq \kappa$. For this we should relax the requirements “$(\bar{a}_s : s \in \{s(\beta) : \beta \in \mathcal{C} \text{ or } s \in I_3\})$ is weakly $(\kappa, \varphi(x, y))$-skeleton like” to

\[(\ast)\] for every $\bar{a} \in \ell^g(\mathcal{X}) \mathcal{M}$ there is $J_\emptyset$ such that:

(i) $J_\emptyset \subseteq \{s(\beta) : \beta \in \mathcal{C}\} \cup I_\emptyset$

(ii) $J_\emptyset \cap \{s(\beta) : \beta \in \mathcal{C}\}$ is a bounded subset of $\{s(\beta) : \beta \in c\mathcal{C}\}$

(iii) $J_\emptyset \cap I_\emptyset$ has cardinality $< \kappa$

(iv) if $s, t \in \{\{s(\beta) : \beta \in \mathcal{C}\} \cup I_\emptyset\} \backslash J_\emptyset$ realizes the same Dedekind cut of $\{\{s(\beta) : \beta \in \mathcal{C}\} \cup I_\emptyset\}$ then $M \models \varphi[\bar{a}_s, a] \equiv \varphi[\bar{a}_t, a]$ and $M \models \varphi[\bar{a}, \bar{a}_s] \equiv \varphi[\bar{a}, \bar{a}_t]$.

2) As mentioned above clause (c) in 3.32 is redundant, but using this has some consequences here.

Theorem 3.24. Suppose that $\lambda > \kappa$, $K_\lambda$ is a family of $\tau$-models, each of cardinality $\lambda, \varphi(x, y)$ is an asymmetric formula with vocabulary $\subseteq \tau$, and $\ell^g(x) = \ell^g(y) < \aleph_0$. Further, suppose that for every linear order $J$ of cardinality $\lambda$ there are $M \in K_\lambda$ and $\bar{a}_s \in M$ for $s \in J$ such that $(\bar{a}_s : s \in J)$ is weakly $(\kappa, \varphi(x, y))$-skeleton like in $M$.

Then, in $K_\lambda$, there are $2^\lambda$ pairwise non-isomorphic models.

Proof. First let $\lambda > \aleph_0$ be regular.

By 3.11(1) there are linear order $I_\zeta$ (for $\zeta < 2^\lambda$) each of cardinality $\lambda$, such that $\text{inv}^\lambda(I_\zeta)$ are well defined and pairwise distinct. Let $J_\zeta$ relate to $I_\zeta$ as guaranteed by 3.22(1). Let $M_\zeta \in K_\lambda$ be such that there are $\bar{a}_s \in M_\zeta$ for $s \in J_\zeta$ such that $(\bar{a}_s : s \in J_\zeta)$ is weakly $(\kappa, \varphi(x, y))$-skeleton like inside $M_\zeta$ (exists by an assumption). By 3.22(1), that is by our choice of $J_\zeta$, we have

$$\text{inv}^\lambda(I_\zeta) \in \text{INV}^\lambda_\kappa(M_\zeta, \varphi(x, y)).$$

Clearly,

$$M_\zeta \cong M_\xi \Rightarrow \text{INV}^\lambda_\kappa(M_\zeta, \varphi(x, y)) = \text{INV}^\lambda_\kappa(M_\xi, \varphi(x, y)),$$

and hence

$$M_\zeta \cong M_\xi \quad \Rightarrow \quad \text{inv}^\lambda_\kappa(I_\zeta) \in \text{INV}^\lambda_\kappa(M_\zeta, \varphi(x, y)).$$

So if for some $\xi < 2^\lambda$, the number of $\zeta < 2^\lambda$ for which $M_\zeta \cong M_\xi$ is $> \lambda$, then $\text{INV}^\lambda_\kappa(M_\zeta, \varphi(x, y))$ has cardinality $> \lambda$ (remember $\text{inv}^\lambda_\kappa(I_\zeta)$ were pairwise distinct for $\zeta < 2^\lambda$). But this contradicts 3.17(1).

So
\[
\{ (\zeta, \xi) : \zeta, \xi < 2^\lambda \text{ and } M_\zeta \cong M_\xi \},
\]
which is an equivalence relation on \(2^\lambda\), satisfies: each equivalence class has cardinality \(\leq \lambda\). Hence there are \(2^\lambda\) equivalence classes and we finish.

For \(\lambda\) singular the proof is similar. If \(\text{cf}(\lambda) > \kappa\), we can choose \(\theta = \text{cf}(\lambda)\) and use \(\text{INV}^2_{\kappa, \theta}\), \(\text{E}59\), \(\text{E}51\) instead of \(\text{INV}^1_{\kappa, \theta}\), \(\text{E}51\), \(\text{E}52\) respectively.

If \(\text{cf}(\lambda) \leq \kappa\), let \(\theta = \kappa^+\) so \(\lambda > \theta > \kappa + \text{cf}(\lambda)\). Hence we can find a mapping

\[
h : \{ \delta < \theta : \text{cf}(\delta) \geq \kappa \} \rightarrow \{ \mu : \mu = \text{cf}(\mu) < \lambda \}
\]
such that for each \(\mu = \text{cf}(\mu) < \lambda\) the set

\[
\{ \delta < \theta : \text{cf}(\delta) \geq \kappa \text{ and } h(\delta) \geq \mu \}
\]
is stationary. Now we can use \(\text{INV}^2_{\kappa, \theta}\), \(\text{E}59\), \(\text{E}51\) instead of \(\text{INV}^1_{\kappa, \theta}\), \(\text{E}51\), \(\text{E}52\) respectively.

Alternatively, for singular \(\lambda\) see the proof of \(\text{E}20\) and \(\text{E}20\) case (d) below.

**Conclusion 3.25.** 1) If \(T_1\) is a first order, \(\lambda \geq |T_1| + N_1\), then there are \(2^\lambda\) pairwise non-isomorphic models of \(T\) of cardinality \(\lambda\) which are reducts of models of \(T_1\).

2) If \(\lambda \geq |T_i| + \kappa^+, \lambda = \lambda^{<\kappa}\), \(\kappa\) is regular, then there are \(2^\lambda\) pairwise non-isomorphic models of \(T\) of cardinality \(\lambda\) which are reducts of models \(M_\lambda^i\) of \(T_1\) such that \(M_i, M_\lambda^i\) are \(\kappa\)-compact and \(\kappa\)-homogeneous. [Really we can get strongly homogeneous; see \(\text{E}36\), \(\text{E}37\)].

3) Assume that \(\psi \in L_{\kappa^+, \kappa_0} (\tau_1), \tau \subseteq \tau_1\), \(\psi\) has the order property for \(L_{\kappa^+, \kappa_0} (\tau)\), i.e., for some formula \(\varphi(x, y) \in L_{\kappa^+, \kappa_0} (\tau)\) satisfying \(\ell_\gamma(\varphi) = \ell_\gamma(\gamma) < \kappa_0\), for arbitrarily large \(\mu\), there is a model \(M\) of \(\psi\) and \(a_i \in M\) for \(i < \mu\) such that

\[
M \models \varphi[a_i, a_j] \text{ iff } i < j.
\]

Then for \(\lambda \geq \kappa + N_1\), \(\psi\) has \(2^\lambda\) models of cardinality \(\lambda\), with pairwise non-isomorphic \(\tau\)-reducts.

**Proof.** 1) Let \(\varphi = \varphi(\bar{x}, \bar{y})\) be a first order formula exemplifying “\(T\) is unstable” (see Definition \(\text{E}59\)). By \(\text{E}59\), \(\text{E}51\) there is a template \(\Phi\) proper for linear orders such that \(|\tau_0| = |\tau_1|\) and for any linear order \(I, \text{EM}(I, \Phi)\) is a model of \(T_1\) satisfying \(\varphi[a_s, a_t]\) if and only if \(I = s < t\). Clearly \(\text{EM}(\tau_0(I, \Phi))\) has cardinality \(\geq |I|\) but \(\leq |\tau_0| + |I| + N_0\). So for every \(\lambda \geq |T_1| + N_0 = |\tau_0| + N_0\) and linear order \(I\) of cardinality \(\lambda\) the model \(M = \text{EM}(\tau_0(I, \Phi))\) is a \(\tau(I)\)-model, a reduct of a model of \(T_1\), hence \(M\) is a model of \(T\) of cardinality exactly \(\lambda\), and by \(\text{E}51\) (4) the sequence \(\langle a_t : t \in I \rangle\) is weakly \(\kappa\)-skeleton like in \(M\). So we have the assumption of \(\text{E}24\), hence its conclusion as required.

2) By \(\text{E}36\), \(\text{E}20\), or case II of the proof of Theorem \(\text{E}1\) (there) we have the assumption of \(\text{E}24\); but \(\text{E}36\), \(\text{E}20\) supersedes upon this.

3) See \(\text{E}18\) (3) and Definition \(\text{E}15\) why the assumption of \(\text{E}24\) holds.

**Remark 3.26.** Also \(\text{E}23\) is a similar result.
§ 3(D). Using Infinitary Sequences.

Now we turn our attention to the case in which the sequences on which \( \varphi(x, y) \) speaks are infinite. We shall need at some point in Theorem \#29 the following:

\textbf{Fact 3.27.} If \( \tau_2 = \tau_1 \cup \{ c_i : i \in I \} \), \( c_i \) are individual constants, \( K_\ell \) is a class of \( \tau_\ell \)-models (for \( \ell = 1, 2 \)), \( M \models K_2 \Rightarrow M \models \tau_1 \models K_1 \), and \( \mu = \mathcal{I}(\lambda, K_2) > \lambda^{|I|} \), then \( \mathcal{I}(\lambda, K_1) \geq \mu \) (so if \( \mu = 2^{\lambda^{|\tau_1|}} \), equality holds).

\textit{Proof.} Straightforward (or see [Sh:c, Ch.VIII,1.3]). \( \square \)

\textbf{Definition 3.28.} We say \( \langle \bar{a}_s : s \in I \rangle \) is weakly \((\kappa, \mu, < \lambda, \varphi(x, y))\)-skeleton like inside \( M \), if \( \mu = \lambda \) we may omit \( \mu \) iff:

(i) \( s, t \in I \) we have

\[ M \models \varphi[\bar{a}_s, \bar{a}_t] \text{ if and only if } I \models s < t, \]

(ii) for every \( \bar{c} \in \mathcal{F}(\bar{a}) M \) for some \( J \subseteq I \), \( |J| < \kappa \) and (*) of \#21(1) holds, and

(iii) moreover, for each \( A \subseteq M, |A| < \mu \), there is \( J \subseteq I \), \( |J| < \lambda \) such that for every \( \bar{c} \in \mathcal{F}(\bar{a}) A \), the statement (*) of \#21 holds for \( J \).

\textbf{Theorem 3.29.} Suppose \( \partial < \kappa < \lambda \) are cardinals, \( \kappa \) regular. Assume \( K \) is a class of \( \tau \)-models, \( \varphi = \varphi(x, y) \) is a formula with vocabulary \( \subseteq \tau \), and \( \partial = \lg(\bar{x}) = \lg(\bar{y}) \), and

(*) \( K = K_\lambda \) and for every linear order \( I \) of cardinality \( \lambda \) there are \( M_I \in K_\lambda \) and a sequence \( \langle \bar{a}_s : s \in I \rangle \) which is weakly \((\kappa, \varphi(x, y))\)-skeleton like inside \( M_I \).

We can conclude that \( \mathcal{I}(K) = 2^\lambda \) if at least one of the following conditions holds:

(a) \( \lambda = \lambda^\partial \)

(b) \( \lambda^\kappa < 2^\lambda \)

(c) We replace the assumption (*) by:

\( (*)_0 \quad K = K_\lambda, \)

\( (*)_1 \quad \lambda^\partial < 2^\lambda, \ cf(\lambda) > \partial, \)

\( (*)_2 \) for every linear order \( J \) of cardinality \( \lambda \) there are \( M_J \in K_\lambda \) and a weakly \((\kappa, < \lambda, \varphi(x, y))\)-skeleton like inside \( M_J \) sequence \( \langle \bar{a}_s : s \in J \rangle \) (where \( \bar{a}_s \in \mathcal{F}[M_J] \), see Definition \#28 below).

(d) We replace the assumption (*) by: for some \( \lambda(0) \leq \lambda(1) \leq \lambda \leq \lambda(3) < 2^\lambda, \mu(0) \leq \mu(1) \leq 2^\lambda \) with \( \lambda(1) \) and \( \mu(1) \) being regular, we have:

\( (*)_0 \quad K = K_{\lambda(3)}, \)

\( (*)_1 \quad \lambda^\partial < 2^\lambda, \)

\( (*)_2 \) for every linear order \( J \) of cardinality \( \lambda \) there is \( M_J \in K_{\lambda(3)} \) (of cardinality \( \lambda(3) \)) and \( \langle \bar{a}_s : s \in J \rangle \) (where \( \bar{a}_s \in \mathcal{F}[M_J] \) which is weakly \((\kappa, \lambda(0), < \lambda(1), \varphi(x, y))\)-skeleton like inside \( M_J \) (see Definition \#28 below),
(*)_{3,\mu(0),\lambda(0)} for \( J \in K^\kappa_\lambda \) and a set
\( A \subseteq M_J \) \((M_J \text{ is from } (*)_2)\) if \(|A| < \lambda(0)\) then:
(i) \( \mu(0) > |S^{\kappa,\kappa}_{\phi,\psi}(A,M_J)|\), or at least
(ii) \( \mu(0) > |\{ \text{Av}_{\{\varphi,\psi\}}(\langle b_i : i < \kappa \rangle, A, M_J : b_i \in A \text{ for } i < \kappa, \text{ the average is well defined and is realized in } M] \}|\),
where
\[ \text{Av}_\Delta(\langle b_i : i < \kappa \rangle, A, M_J) := \{ \varphi(\vec{x},\vec{a})^k : \varphi(\vec{x},\vec{y}) \in \Delta, \vec{t} \text{ a truth value, } \vec{a} \in A \text{ and } \text{for all but a bounded set of } i < \kappa, M_J \models \varphi[b_i,\vec{a}]^k \}, \]

\begin{align*}
(*)_4 & \lambda,\mu(1),\mu(0),\lambda(0) \text{ if } I_j \subseteq \delta^\lambda(3) \text{ and } |I_j| = \lambda \text{ for } i < \mu(1), \text{ then for some } B \subseteq \lambda(3) \text{ we have:} \\
|B| & < \lambda(0) \text{ and } [|i : |I_i \cap B| \geq \kappa)| \geq \mu(0). \\
(c) & \text{ We replace assumption } (*) \text{ by: for some } \lambda_0,\epsilon \leq \lambda_1,\epsilon \leq \lambda, \mu_0,\epsilon \leq \mu_1 \leq 2^\lambda, \text{ for } \epsilon < \epsilon(*), \mu_1 \text{ is regular and:} \\
(*)_0 & K = K_{\lambda_0}, \\
(*)_1 & \lambda_0 < 2^\lambda, \\
(*)_2 & \text{ for every linear order } J \text{ of cardinality } \lambda \text{ there is } M_J \in K_{\lambda(3)} \\
& \text{ and } \langle a_s : s \in J \rangle \text{ (where } a_s \in (\theta(M_J)) \text{) which for each } \epsilon < \epsilon(*) \text{ is weakly } (s_1, < \lambda_0, i, < \lambda_1, i, \varphi(\vec{x},\vec{y}))\text{-skeleton like inside } M_J, \\
(*)_3 & \mu_0,\epsilon,\lambda_0,\epsilon \text{ if } \epsilon < \epsilon(*) \text{ and } J \in K^\kappa_\lambda \text{ and a set } A \subseteq M_J \text{ (} M_J \text{ is from } (*)_2) \text{ if } |A| < \lambda_0,\epsilon \text{ then:} \\
(i) & \mu_0,\epsilon > |S^{\kappa,\kappa}_{\phi,\psi}(A,M_J)| \text{ or at least} \\
(ii) & \mu_0,\epsilon > |\{ \text{Av}_{\{\varphi,\psi\}}(\langle b_i : i < \kappa \rangle, A, M_J) : b_i \in A \text{ for } i < \kappa, \text{ the average is well defined and is realized in } M] \}|,
\end{align*}

\[ \text{Av}_\Delta(\langle b_i : i < \kappa \rangle, A, M_J) := \{ \varphi(\vec{x},\vec{a})^k : \varphi(\vec{x},\vec{y}) \in \Delta, \vec{t} \text{ a truth value, } \vec{a} \in A \text{ and for all but a bounded set of } i < \kappa, M_J \models \varphi[b_i,\vec{a}]^k \}, \]

\begin{align*}
(*)_4 & \text{ there are } h_\alpha : \lambda \rightarrow \{ \theta : \theta \text{ regular, } \epsilon \leq \theta \leq \lambda \} \text{ for } \alpha < 2^\lambda \text{ such that: if } S \subseteq 2^\lambda, |S| \geq \mu_1(1) \text{ and } f_\alpha : \lambda \rightarrow (\delta(3)) \text{ for } \alpha \in S, \text{ then we can find } \epsilon < \epsilon(*), B \subseteq \lambda_3 \text{ satisfying: } |B| < \lambda_0,\epsilon \text{ and the set } \{ \zeta : \text{ the closure of } \{ \zeta : f_\alpha(\zeta) \subseteq B \} \text{ has a member } \delta \text{ of cofinality } \kappa \text{ such that } h_\alpha(\delta) \geq \lambda_1,\epsilon \text{ has } \mu_0,\epsilon \text{ members.} \\
\text{[Note: cf}(\delta) & = \kappa' \geq \kappa \text{ can be allowed if } (*)_3,\mu_0,\epsilon,\lambda_0,\epsilon \text{ is changed accordingly}. \\
(f) & \text{ For some } \mu < \lambda, \text{ there is a linear order of cardinality } \mu \text{ with } \geq \lambda \text{ Dedekind cuts each with upper and lower cofinality } \geq \kappa \text{ and } 2^{\mu+\theta} < 2^\lambda. \\
(g) & \text{ there is } \mathcal{P} \subseteq [\lambda^\kappa]^\kappa \text{ of cardinality } < 2^\lambda \text{ such that every } X \subseteq \lambda^\theta \text{ of cardinality } \lambda \text{ contains at least one of them (and (*)_4) \text{ (can use similar considerations in other places).} \\

\text{Proof. Case (a):} \\
\text{In Definition } \mathcal{P}_{\lambda^\theta} \text{ we can replace } A \text{ by } J, \text{ a set of sequences of length } \theta \text{ from } M, \text{ which means that clause } (i) \text{ in } \langle \alpha \rangle \text{ of } \mathcal{P}_{\lambda^\theta} \text{ now becomes:}
(i)' for every large enough \( t \in I \), for every \( \bar{b} \in \hat{J} \) we have \( M \models \varphi[\bar{c}, \bar{b}] = \varphi[\bar{a}_t, \bar{b}] \) and \( M \models \psi[\bar{c}, \bar{b}] \equiv \psi[\bar{a}_t, \bar{b}] \).

Thus in Definition \( \lambda E59 \), replace \( \langle A_i : i < \lambda \rangle \) by \( \langle \hat{J}_i : i < \text{cf}(\lambda) \rangle \), \( \partial \mid M \mid = \bigcup_i \hat{J}_i, |\hat{J}_i| < \lambda, \hat{J}_i \) increasing continuous with \( i \). No further changes in \( \lambda E59 \) is needed.

Alternatively, we can define \( N = F_\partial(M) \) as the model with universe \( |M| \cup \partial |M| \), assuming of course \( |M| \) is disjoint to \( \partial |M| \) such that

\[
\tau(N) = \tau(M) \cup \{ F_i : i < \partial \},
\]

\[
R^N = R^M \text{ for } R \in \tau(M),
\]

\[
G^N(x_1, \ldots, x_n) = \begin{cases} 
G^M(x_1, \ldots, x_n), & \text{if } x_1, \ldots, x_n \in |M|; \\
\{ x_1 \}, & \text{otherwise}
\end{cases}
\]

for function symbol \( G \in \tau(M) \) which has \( n \)-places and

\[
F^N_i(x) = \begin{cases} 
x(i) & \text{if } x \in \partial M, \\
x & \text{if } x \in M
\end{cases}
\]

for \( i < \partial \), so \( F_i \) is a new, unary function symbol for \( i < \partial \).

Note that \( |M_1| \cong M_2 \) if and only if \( F_\partial(M_1) \cong F_\partial(M_2) \), and \( ||F_\partial(M)|| = ||M||^\partial \), etc. So we can apply \( \lambda E59 \) to the class \( \{ F_\partial(M) : M \in K_\lambda \} \) and the formula \( \varphi'(x, y) = \varphi(F_i(x) : i < \partial), (F_i(y) : i < \partial) \) and we can get the desired conclusion.

Case (b): We use weakly \( (\kappa, \varphi(\bar{x}, \bar{y})) \)-skeleton like sequences \( \langle \bar{a}_s : s \in \kappa + (I_\lambda)^+ \rangle \)

in \( M_\zeta \in K_\lambda \) for \( \zeta < 2^\lambda \), with \( \langle \text{inv}_\zeta(I_\lambda) : \zeta < 2^\lambda \rangle \) pairwise distinct, and count the number of models \( \langle M_\zeta, \langle \bar{a}_s : s \in \kappa \rangle \rangle \) up to isomorphism. Then “forget the \( \bar{a}_s, s \in \kappa \), i.e., use \( \lambda E27 \) below.

Case (c): We revise \( \lambda E14 \) to \( \lambda E17 \); we use this opportunity to present another reasonable choice in clause (a) of \( \lambda E14 \).

Change 1: In \( \lambda E14(\alpha) \) we replace (i), (ii) by

(i)' for every formula \( \partial(\bar{x}, \bar{d}) \in tp(\varphi(\bar{x}, \bar{y}), \psi(\bar{x}, \bar{y}))(\bar{c}, A, M) \), for every large enough \( t \in I \) we have \( M \models \partial[\bar{c}, \bar{d}] \equiv \partial[\bar{a}_t, \bar{d}] \),

(ii)' \( \langle \bar{a}_s : s \in J + (J)^+ \rangle \) is weakly \( (\kappa, \varphi(\bar{x}, \bar{y})) \)-skeleton like inside \( M \),

(iii)' \( \theta > \text{cf}(J) \), (actually \( \theta \neq \text{cf}(J) \) would suffice, but no real need).

Of course, the meaning of Definition \( \lambda E14(\beta)-(\delta) \) changes, and the reader can check that, e.g., the proof of the Fact \( \lambda E15 \) is still valid.

Change 2: In Definition \( \lambda E17(1) \), inside the definition of \( \text{INV}_\alpha^\omega \), we demand \( \text{cf}(d) = \lambda \) recalling \( \lambda \) is regular.

Change 3: In Definition \( \lambda E17(2) \), inside the definition of \( \text{INV}_\alpha^\omega \), add \( \text{cf}(d) > \text{cf}(\delta) \) (necessitate by change 1, actually \( \text{cf}(d) \neq \text{cf}(\delta) \) suffices).

Change 4: In Definition \( \lambda E17(3) \) demand \( \text{cf}(\lambda) > \partial \).
\textbf{Change 5:} In \textbf{1.17}, in all cases the "cardinality $\leq \lambda$" is replaced by "cardinality $\leq \lambda^+$" and part (2) becomes like part (3).

\textbf{Change 6:} We replace "$(k, \varphi(x, y))$-skeleton like" by $(k, < \lambda, \varphi(x, y))$-skeleton like. In \textbf{3.22}(3) add the demand $\text{cf}(\lambda) > \delta$, $h(i) > \text{cf}(i)$.

\textbf{Change 7:} Inside the proof of \textbf{3.22}(1), now not for every $\bar{a} \in \mathcal{E}(x)M$ we define $J_a$, but for every $A \subseteq M$ of cardinality $< \lambda$ we choose $J_A \subseteq J$, $|J_A| < \lambda$ by Definition \textbf{p32}, and in $(*)$ in the proof there we demand

$$(\forall \alpha < \delta)(\exists \beta < \delta)[\bigcup_{s \in J_{A_{\alpha}}} \bar{a}_s \subseteq A\beta].$$

\textbf{Change 8:} In the proof of \textbf{3.22}(2) let $\langle I_i : i < \theta \rangle$ be as in the statement of \textbf{3.22}(2), and let $\bar{J} = \sum_{i < \theta} I^*_i$, and assume $\langle \bar{a}_s : s \in \bar{J} \rangle$ is $(k, < \lambda, \varphi(x, y))$-skeleton like inside $M \subseteq K_\lambda$. So let $\langle A_i : i < \theta \rangle$ be a representation of $M$, and for each $i < \theta$ let $J_{A_i} \subseteq J, |J_{A_i}| < \lambda$ be as in Definition \textbf{p32}.

Define

$$\mathcal{C} = \{ \delta < \theta : \delta \text{ is a limit ordinal such that for every } \alpha < \delta \text{ the cardinality of } J_{A_{\alpha}} \text{ is } < \lambda_{S_{\alpha}} \}. $$

So let $\delta \in C, \text{cf}(\delta) \geq \kappa$. Recall that $\text{cf}(I_\delta) > \lambda_\delta$ so clearly we can find $s(\delta) \in I_{S_{\delta}}$ such that

$$I_\delta \models s(\delta) \leq s \Rightarrow s \notin \bigcup_{i < \delta} J_{A_i}.$$ 

Now $(\bar{c}_{s(\delta)}, A_{\delta}, M, \varphi(x, y))$ is as required.

\textbf{Change 9:} In the proof of \textbf{3.28}(3) let $J = \sum_{\alpha < \theta} I^*_\alpha$ and $M, \langle \bar{a}_s : s \in J \rangle, \langle A_i : i < \text{cf}(\lambda) \rangle, J_{A_i} \subseteq J$ be as above, and let $s(\alpha) \in I_{S_{\alpha}}$. As $\text{cf}(\lambda) > \delta$ by $(*)$ of the assumption, for each $s \in J$ for some $i(s) < \text{cf}(\lambda)$ we have $\bar{c} \subseteq A_{i(s)}$, but $\theta = \text{cf}(\theta) > \text{cf}(\lambda)$ hence for some $i(s) < \text{cf}(\lambda)$ the set $W = \{ \alpha < \theta : i(\alpha) \leq i(s) \}$ is unbounded in $\theta$. Let $\mathcal{C} = \{ \delta < \theta : \delta \geq \sup(\delta \cap W) \}$. We can choose $\delta \in \mathcal{C}$ of cofinality $\geq \kappa$ such that $h(\delta) > |J_{A_{i(s)}}|$, and continue as in the previous case.

\textbf{Change 10:} Proof of \textbf{3.21}(2) (necessitated by change 1)

We shall use Lemma \textbf{3.17} (with $I^1, I^2$ here standing for $I, J$ there and $\psi$ for $\varphi$). Conditions (b), (c) from \textbf{3.10} are met trivially and by similar arguments in condition (a) it is enough to prove clause (a).

Let us prove (a)$(\alpha)$ from \textbf{3.10}. Let $I^1 \subseteq I'$ be unbounded of order type $\text{cf}(I') = \theta$ and let $J^1 \subseteq J'$ be unbounded of order type $\text{cf}(J')$, which is $\neq \theta$. Possibly shrinking those sets the truth values of $\varphi(\bar{a}_1, \bar{a}_2)$ when $s \in I^1, y \in J^2 \land (\exists x)(t' \in J^2 \land t' <_{J_2} t)$ is constant. We can continue as before.

Note that if $\text{cf}(\lambda) > \kappa$ this follows from case (d). If $\lambda$ is regular, choose $\lambda(0) = \lambda(1) = \lambda(3) = \lambda$ and $\mu(0) = \mu(1) = (\lambda^+)^+$ and now the assumptions hold. If $\lambda$ is singular, let $\epsilon(\star) = \text{cf}(\lambda), \chi = (\text{cf}(\lambda) + \kappa)^+ \leq \lambda, \mu_0 = \mu_{1, \epsilon} = (\lambda^+)^+$ and let $\{ (\lambda_0, \lambda_1) : \epsilon < \epsilon(\star) \}$ list $\{ (\lambda_1, \lambda_3) : i < j < \text{cf}(\lambda) \}$ and choose $h_\lambda = h : \lambda \longrightarrow \prod_{\alpha < \omega_1} \aleph_\alpha$ and so on.
\{ \theta : \theta \text{ regular, } \kappa \leq \theta \leq \lambda \} \text{ such that } \epsilon < \epsilon(*) = cf(\lambda) \text{ implies } \{ \delta < \chi : cf(\delta) = \kappa \text{ and } h(\delta) = \epsilon \} \text{ is stationary. Now we can apply case (e).}

Case (d): Let \langle I_\alpha : \alpha < 2^\lambda \rangle \text{ be a sequence of linear orders of cofinality } cf(\lambda(1)) = \lambda(1), \text{ each of cardinality } \lambda, \text{ with pairwise distinct inv}_2^\kappa(I_\alpha) \text{ if } \lambda \text{ is regular, inv}_3^\kappa(I_\alpha) \text{ if } \lambda \text{ is singular exists by } p343.11. \text{ Let } J_\alpha = \sum_{\zeta \leq \lambda} I^*_\alpha, \zeta, \text{ where } I^*_{\alpha,\zeta} \text{ are pairwise disjoint, } I_{\alpha,\zeta} \cong I_\alpha. \text{ Let } M_{J_\alpha} \text{ be a model as guaranteed in (*)2 with } \langle \bar{a}_s : s \in J_\alpha \rangle \text{ as there. Suppose } \{ M_{J_\alpha}/\cong : \alpha < 2^\lambda \} \text{ has cardinality } < 2^\lambda, \text{ then without loss of generality } M_{J_\alpha} = M_{J_0} \text{ for } \alpha < \mu(1) \text{ and without loss of generality } M_{J_\alpha} \text{ has universe } \lambda(3). \text{ Let } s(\alpha,\zeta) \in I_{\alpha,\zeta}, \text{ so } \dot{I}_\alpha := \{ \bar{a}_{s(\alpha,\zeta)} : \zeta < \lambda \} \text{ is a subset of } ^3(\lambda(3)) \text{ of cardinality } \lambda. \text{ By (*)4,\lambda,\mu(1),\mu(0),\lambda(0) there is } B \subseteq \lambda(3), \text{ } |B| < \lambda(0) \text{ such that }

\[ S := \{ \alpha < \mu(1) : |\dot{I}_\alpha \cap ^3B| \geq \kappa \} \]

has cardinality \( \geq \mu(0) \). Choose for each \( \alpha \in S \) a set

\[ S_\alpha \subseteq \{ \zeta : \bar{a}_{s(\alpha,\zeta)} \subseteq B \} \]

which has order type \( \kappa \), and let

\[ \delta_\alpha := \sup(S_\alpha). \]

Clearly \( \delta_\alpha \leq \lambda \), hence \( I_{\alpha,\delta_\alpha} \) is well defined. For each \( \alpha \in S \), as \( \langle \bar{a}_s : s \in J_\alpha \rangle \) is \( (\kappa,\lambda(0),< \lambda(1),_\varphi(\bar{x},\bar{y}))\)-skeleton like and \( |B| < \lambda(0) \), there is a subset \( J_{\alpha,B} \) of \( J_\alpha \) as in Definition p328. But \( I_{\alpha,\delta_\alpha} \) has cofinality \( \lambda(1) > |B| \), hence for all large enough \( t \in I_{\alpha,\delta_\alpha} \), the type \( tp_{(\varphi,\psi)}(\bar{a}_t,B,M_{J_0}) \) is the same; choose such \( t_\alpha \). Clearly (for \( \alpha \in S \))

\[ tp_{(\varphi,\psi)}(\bar{a}_{t_\alpha},B,M_{J_0}) = Av_{(\varphi,\psi)}(\langle \bar{a}_{s(\alpha,\zeta)} : \zeta \in S_\alpha \rangle, B, M_{J_0}), \]

so by (*)\( _{\lambda,\mu(0),\lambda(0)} \) from the assumption of case (d) without loss of generality for some \( \alpha \neq \beta \) we get the same type. But \( I_\alpha, I_\beta \) have different (and well defined) inv}_2^\kappa (or inv}_3^\kappa), contradicting p21(2).

Case (e): Similar proof (to (d)).

Case (f): By p27 below.

Case (g): Similar to case (b).
\[3\text{(E)}. \text{ Further Results.}\]

In 3.29 above we do not get anything when \(\lambda^\theta = 2^\lambda\), however if we assume that \(M_\delta\) has a clearer structure, e.g., is an EM-model, we can get better results as done in 3.31 below.

Another aim of this subsection we may like in, for example, 3.25 to get not just non-isomorphic models, but non-isomorphic because of some nice invariant is different. The following definition serves, we shall mainly use semi-\(\kappa\)-obey (hence \(\kappa\)-obey as a step toward it).

\[\text{Definition 3.30. Assume:}\]

\(\hspace{1em}\Box\ (a) \mu\) be a regular uncountable cardinal
\(\hspace{1em}\Box\ (b) \bar{h} = (h_0, h_1), h_0, h_1\) be functions from some stationary \(S \subseteq \mu\) to a set of regular cardinals \(\leq \lambda\) satisfying \((\forall \delta \in S)(h_0(\delta) \leq h_1(\delta))\)
\(\hspace{1em}\Box\ (c) M\) is a \(\tau\)-model
\(\hspace{1em}\Box\ (d) \psi(x, \gamma)\) is a formula in the vocabulary \(\tau\) such that \(\ell g(x) = \ell g(\gamma) = \partial, \kappa = cf(\kappa)\).

1) If \(\delta\) is a limit ordinal, \(\bar{a} = \langle \bar{a}_i : i < \delta \rangle\) and \(\bar{a}_i \in \bar{M}\) for \(i < \delta\) then we let (recall \(\ell g(x) = \partial\), we may omit \("\{\varphi, \psi\}\" as they are constant here):

\(\hspace{1em}\Box\ (a) Av_{\varphi, \psi}(\bar{a}, M) = \{g(\bar{x}, \bar{b}) : \bar{g} \in \{\varphi, ~\varphi, \varphi_2 \neg \psi\} \text{ and } \bar{b} \in \bar{M}\}\)
\(\hspace{1em}\Box\ (b) \mathcal{P}_{M, \alpha, \psi}(\bar{a}, M) = \{B \subseteq M : \text{the type } Av_{\varphi, \psi}(\bar{a}, M)|B \text{ is realized in } M\}\).

2) Assume \(\bar{A} = (A_i : i < \mu), A_i \subseteq M\) and \(\mathcal{C}\) is a club of \(\mu\). We say \((M, \bar{A}, \mathcal{C}) - \kappa\)-obey \((\bar{h}, \varphi)\) when \((A) \Rightarrow (B)\) where:

\(\hspace{1em}\Box\ (A) \hspace{1em}\Box\ (a) \delta \in \mathcal{C} \cap S \subseteq \mu\) and \(cf(\delta) \geq \kappa\)
\(\hspace{1em}\Box\ (b) \hspace{1em}\Box\ \bar{a} = \langle \bar{a}_i : i < cf(\delta) \rangle\)
\(\hspace{1em}\Box\ (c) \hspace{1em}\Box\ \text{if } i < cf(\delta) \text{ then } (\exists \alpha < \delta)(\bar{a}_i \subseteq A_\alpha)\)
\(\hspace{1em}\Box\ (d) \hspace{1em}\Box\ \text{for every } \alpha < \delta, \text{ the sequence } \langle tp_{\varphi, \psi}(\bar{a}_i, A_\alpha, M) : i < cf(\delta) \rangle \text{ is eventually constant}\)
\(\hspace{1em}\Box\ (e) \hspace{1em}\Box\ \text{every } B \subseteq |M| \text{ of cardinality } < h_0(\delta) \text{ belongs to } \mathcal{P}_{M, \alpha, \psi}(\bar{a}, M)\)
\(\hspace{1em}\Box\ (f) \hspace{1em}\Box\ \langle \bar{a}_i : i < cf(\delta) \rangle \text{ is weakly } (\kappa, \varphi(\bar{x}, \bar{y}))\)-skeleton like in \(M\)
\(\hspace{1em}\Box\ (B) \hspace{1em}\Box\ \text{every } B \subseteq M \text{ of cardinality } < h_2(\delta) \text{ belongs to } \mathcal{P}_{M, \alpha, \psi}(\bar{a}, M); \text{ so if } h_0(\delta) = h_1(\delta) \text{ then this is trivial}\).

3) We say that \(M\) \(\kappa\)-obeys \((\bar{h}, \varphi)\), or \((h_0, h_1, \varphi)\), when there is \(H\) satisfying a function \(H\) from \(\mu^+([M]^{<\mu})\) to \([M]^{<\mu}\) satisfying: if \((A_i : i < \mu)\) is an increasing continuous sequence of subsets of \(M, |A_i| < \mu, \text{ and } H((A_i : i \leq j)) \subseteq A_{j+1}\) for every \(j < \mu\), then for some club \(\mathcal{C} \subseteq \mu\), for every \(\delta \in \mathcal{C} \cap \mathcal{S}\) of cofinality \(> \kappa\) the triple \((M, A, \mathcal{C})\) does \(\kappa\)-obeys \((\bar{h}, \varphi)\).

4) We say that the triple \((M, A, \mathcal{C}) - \kappa\)-obeys \((\bar{h}, \varphi)\) exactly when for every \(\delta \in \mathcal{C} \cap S\) with \(cf(\delta) \geq \kappa\), for some \(\bar{a}\) as in clause (A) of part (2), some \(B \subseteq M\) of cardinality \(h_1(\delta)\), does not belong to \(\mathcal{P}_{M, \alpha, \psi}(\bar{a}, M)\).
(β) we say that the model $M$ does $\kappa$-obey $(\bar{h}, \varphi)$ exactly as in part (3) but in the end we strengthen the conclusion to “$(M, \bar{a}, S)$ does $\kappa$-obey $(\bar{h}, \kappa)$ exactly”.

5) (α) We say that the triple $(M, \bar{A}, \bar{C})$ weakly $\kappa$-obey $(\bar{h}, \varphi)$ as in part (2) only replacing clause (A)(f) by $(A)(f)^+$

• if $B \subseteq M$ has cardinality $< h_0(\delta)$ then $B \cup A_\delta \in \mathcal{P}_{M, a, \bar{C}}$

(β) We say that the model $M$ does $\kappa$-obey $(\bar{h}, \varphi)$ exactly as in part (3) but in the end we weaken the conclusion to “$(M, \bar{a}, S)$ weakly $\kappa$-obey $(\bar{h}, \kappa)$ exactly”.

6) (α) We define “$(M, \bar{A}, \bar{C})$ weakly $\kappa$-obeys $(\bar{h}, \varphi)$ exactly” as in part (4)(α) replacing “$\kappa$-obey” by “weakly $\kappa$-obey

(β) We define “$M$ weakly $\kappa$-obey $(\bar{h}, \varphi)$ exactly as in part (4)(β) replacing $\kappa$-obey” by “weakly $\kappa$-obeys”.

7) (α) We say the quadruple $(M, \bar{A}, \bar{C}, \bar{b})$ semi-$\kappa$-obeys $(\bar{h}, \varphi)$ when

(A) (a)-(e) as in part (2)

(f) $\bar{a}_i \in \{\bar{b}_\beta : \beta < \delta\}$

(B) we say “the model $M$ semi-$\kappa$-obeys $(\bar{h}, \varphi)$” as in part (3) when for some $\bar{a} = (\bar{b}_i : i < \mu), b_i \in \delta M$ and function $F$ from $\kappa \times [\mu]^{< \mu}$ into $[\kappa \times \delta]^{< \kappa}$ we have: as in part (3) but in the end $(M, \bar{A}, \bar{C}, \bar{a})$ semi-$\kappa$-obeys $(\bar{h}, \varphi)$.

8) We say “exactly semi $\kappa$-obeys $(h_0, h_1, \varphi)$” when $M$ semi-$\kappa$-obeys $(h_0, h_1, \varphi)$ and if $\bigwedge_{\delta \in \delta} h_1(\delta) < \kappa$ and $(h_1(\delta) < h_1^+(\delta))$, then $M$ does not semi-$\kappa$-obeys $(h_0, h_1^+, \varphi)$. We write $(h, \varphi)$ if in $(h_0, h_1, \varphi), h_1 = h$ and $h_0$ is constantly $\kappa$.

Remark 3.31. 1) In [Fr:30(5), (6)] we can avoid $\langle a_i : i < \kappa(\delta) \rangle$ with small changes.

2) Note that assuming below $\lambda < \kappa^{< \theta}$ is very reasonable as $\kappa^{< \theta}$ is the number of distinct terms, and we have no information on a representation in $M_{\kappa, \theta}(I)$ using every term only once. Also $\lambda < \theta_+^+$ seems reasonable.

The following facts will be used in the proof of 2.$\Theta$.

Fact 3.32. Assume that $(2^{\kappa^+} : i < \kappa)$ is strictly increasing and $\mu = \sum (\lambda_i : i < \delta) < 2^{\kappa^+}$. Then for arbitrarily large regular cardinals $\lambda < \mu$ there is tree with $< \mu$ nodes and $\geq 2^{\kappa^+}, \kappa$-branches (hence a linear order of cardinality $< \mu$ with $\geq 2^{\kappa^+} > \mu$ Dedekind cuts with both cofinality exactly $\lambda$).

Remark 3.33. This is used in [Sh:430, t32=Lt20] and will be used in proving the properties from [Sh:511].

Proof. By [Sh:430, p34].
The following is used in the proof of F.36.

**Fact 3.34.** Assume $\chi \leq \mu = \mu^{<\theta} < \lambda$ and the linear order $J^{[\chi]}$ are from [Sh:E62, 2.16=Lb60(5)] with $(\mu, \mu^+, \mu^+, \aleph_0)$ here standing for $(\lambda, \mu_1, \mu_2, \theta)$ there and for $I \in K^\omega_\mu$ we define $M_I$ naturally, as $M_{I+J^{[\chi]}} \models \{ \sigma(\bar{t}) : \sigma \text{ a } \tau_{\chi, \theta}-\text{term}, \bar{t} \in {}^{\theta}\langle I + J^{[\chi]} \rangle \}$ (using the fullness of the representations).

Then

\[ \mathbb{E}_1 \text{ if } I_1, I_2 \in K^\omega_\mu, \text{ and } M_{I_1 + J^{[\chi]}} \not\models M_{I_2 + J^{[\chi]}}, \text{ then } M_{I_1 + J^{[\chi]}} \not\models M_{I_2 + J^{[\chi]}}, \]
\[ \mathbb{E}_2 \text{ if } |\{ M_I \models \models I \in K^\omega_\mu \}| \geq |\{ M_{I_1 + J^{[\chi]}} \models \models I \in K^\omega_\mu \}| = |\{ M_I \not\models I \in K^\omega_\mu \}|. \]

**Proof.** The first clause by clause (j) of [Sh:E62, 2.16=Lb60(4)], the second clause follows.

**Fact 3.35.** Let $J^{[\kappa]}$ be a linear order of cardinality $\kappa$ such that $\alpha < \kappa \Rightarrow J^{[\kappa]} \times (\alpha + 1) \cong J^{[\kappa]} \cong J^{[\kappa]} \times ((\alpha + 1)^+)$ (e.g. let $J$ be a $\kappa$-dense strongly $\kappa$-homogeneous linear order, hence $\alpha \leq \kappa \Rightarrow J \times (\alpha + 1) \cong J = J \times ((\alpha + 1)^+)$, and by the L"uvenheim-Skolem argument there is a dense $J' \subseteq J$ of cardinality $\kappa$ with this property; alternatively use [Sh:E62, 2.16=Lb60]).

**Fact 3.36.** Assume

\begin{itemize}
  \item[(a)] $\mu$ is regular $\leq \lambda$, and $(\forall \alpha < \mu)(\kappa + \chi + |\alpha|^{<\theta} < \mu),$
  \item[(b)] $I \in K^\omega_\kappa,$
  \item[(c)] $\langle \alpha_i : \alpha < \mu \rangle$ is $<_I$-increasing,
  \item[(d)] $S = \{ \delta < \mu : \text{cf}(\delta) > \kappa \}$ and $h$ is the function with domain $S$ defined by
  \[ h(\delta) = \text{cf}(I^+ \upharpoonright \{ t : (\forall i < \delta)(t_i < t) \}) \]
\end{itemize}

Then there is a function $H$ from $\mu^{>[M]^{<\mu}}$ to $[M]^{<\mu}$ satisfying $\bigcup \{ a_{t_i} : j < i \} \subseteq H(A_i : j < i)$ and such that:

\[ \forall \text{ if } A_i \in [M]^{<M} \text{ is increasing continuous, } H(A_i : j < i) \subseteq A_{i+1} \text{ and } \]
\[ \mathcal{C} = \{ \delta < \mu : \delta \text{ a limit ordinal such that } (\forall i < \mu)(a_{t_i} \subseteq A_\delta \Leftrightarrow i < \delta) \}, \]

then

\begin{itemize}
  \item[(a)] $\mathcal{C}$ is a club of $\mu,$
  \item[(b)] there is an increasing continuous sequence $(I_\alpha : \alpha < \mu), I_\alpha \subseteq I,$ $I_\alpha < \mu$ such that
    \begin{itemize}
      \item[(i)] $A_\alpha \subseteq \{ \sigma(\bar{t}) : \sigma \text{ an } \tau_{\chi, \theta}-\text{term}, \bar{t} \in {}^{\theta}\langle I_{\alpha+1} \rangle \} \subseteq A_{\alpha+1},$
      \item[(ii)] $t_\alpha \in I_{\alpha+1},$
      \item[(iii)] $\mathcal{C}_1 = \{ \delta \in \mathcal{C} : \text{ if } t_\alpha \in I_\delta \text{ and } (\exists \beta)(t < I_\beta) \Rightarrow (\exists \beta < \delta)(t < I_\beta) \}$ is a club of $\mu,$
      \item[(iv)] $a_{t_\alpha} \subseteq A_{\alpha+1}$
    \end{itemize}
  \item[(c)] if $\delta \in \mathcal{C} \cap S$ there are $\langle \alpha_\epsilon : \epsilon < \text{cf}(\delta) \rangle$, $\langle \beta(\epsilon) : \epsilon < \text{cf}(\delta) \rangle$ increasing with limit $\delta$, such that $a_{t_{\beta(\epsilon)}} \subseteq A_{\alpha_\epsilon},$
  \item[(d)] if $\delta(\alpha_\epsilon, \beta(\epsilon)) : \epsilon < \text{cf}(\delta)$ are as in clause (b) then for each $\alpha < \delta$ the sequence $\langle t_{p_{\alpha, \phi}(a_{t_{\beta(\epsilon)}}), A_\alpha, M} : \epsilon < \text{cf}(\delta) \rangle$ is essentially constant,
(e) if $\beta \subseteq M$, $|\beta| < \text{cf}(\delta) + h(\delta)$ then $p^*_{M,(\check{a}_{\beta}(\delta) : \check{a}_{\beta}<\text{cf}(\delta))} \upharpoonright \beta$ is realized in $M$, see Definition E30(1),(*)_3, so in Definition E30(1),(*)_2’s notation, $[M]^{<\text{cf}(\delta)+h(\delta)} \subseteq \mathcal{P}_\beta$.

(\(\zeta\)) if $\beta \subseteq M$, $|\beta| < h(\delta)$ then $p^*_{M,(\check{a}_{\beta}(\delta) : \check{a}_{\beta}<\text{cf}(\delta))} \upharpoonright (\beta \cup A_\delta)$ is realized in $M$, so in Definition E30(1)(*)_2’s notation, $[M]^{<h(\delta)} \subseteq \mathcal{P}_A$.

(\(\eta\)) there are $B^- \subseteq A_\delta$ of cardinality $\text{cf}(\delta)$ and $B^+ \subseteq M$ of cardinality $h(\delta)$ such that $p^*_{M,(\check{a}_{\beta}(\delta) : \check{a}_{\beta}<\text{cf}(\delta))} \upharpoonright (B^- \cup B^+)$ is omitted by $M$, actually $\{\varphi(\check{a}_{\beta}(\delta)) : i < \text{cf}(\delta)\} \cup \{\varphi(\check{x}, a_i) : i \in J\}$ is omitted for some $J \subseteq [I]^{\text{cf}(\delta)}$.

**Definition 3.37.** We say $N \in K^*$ is almost $\kappa$-homogeneous when:

- if $I \subseteq N$, $|I| < \kappa$ then we can find $J, I \subseteq J \subseteq N$, $|J| < \kappa$ such that
- if $s, t \in (N \setminus J)$ realize the same cut of $J$ and $s \in p^N_\alpha \iff t \in p^N_\alpha$ for every $\alpha < \alpha(*)$, then there is an automorphism of $N$ over $J$ mapping $s$ to $t$.

**Conclusion 3.38.** Assume $h_1 \in \text{Rang}(g_1), h_2 \in \text{Rang}(g_2)$.

1) If $N \in K^\kappa_{h_1,h_2}$, $n < \omega$ and $x_1 < x_2 < \ldots < x_n$ in $N$, and $y_1 < \ldots < y_m$ in $N$, and $x_m \in p^N_\alpha \iff y_m \in p^N_\alpha$ for $\alpha < \alpha(*)$, $m \in \{1, \ldots, n\}$, then there is an automorphism of $N$ mapping $x_m$ to $y_m$ for $m = 1, \ldots, n$.

2) If $N \in K^\kappa_{h_1,h_2}$ and $J \subseteq N$ is quite closed in $M$ then

\(\ast\) if $s, t \in N \setminus J$ realize the same cut of $J$ and $s \in p^N_\alpha \iff t \in p^N_\alpha$ for $\alpha < \alpha(*)$, then there is an automorphism of $N$ over $J$ mapping $s$ to $t$.

3) Every $N \in K^\kappa_{h_1,h_2}$ is almost $\kappa$-homogeneous (where $\kappa \geq \aleph_0$).

4) Assume $N \in K^\kappa_{h_1,h_2}$ and $J_1, J_2 \subseteq N$ are quite closed and $|J_1|$ is unbounded in $N$ if $J_2$ is unbounded in $N$ and $|J_1|$ is unbounded in $N^*$ if $J_2$ is unbounded in $N^*$.

If $f$ is an isomorphism from $N \setminus J_1$ onto $N \setminus J_2$ then we can extend $f$ to an automorphism of $M$.

**Theorem 3.39.** If (A) then (B) where:

(A) for any $I \subseteq K^n_X$

\(\ast\) \(\varphi(x, y)\) is an asymmetric $\tau(\kappa)$-formula, $\varphi = \ell g(\bar{x}) = \ell g(\bar{y})$

\(\ast\) for every $I \in K^n_{\kappa}$ we have $M_I \in K^*$

\(\ast\) $M_I$ weakly $\{\varphi(\check{x}, \check{y})\}$-representation of $M_I$ in $\mathcal{M}_{\kappa}(I)$, by the identity function for transparency, see clause (d) of Definition E32.1

\(\ast\) moreover, $\text{id}^M_{M_I}$ is a full representation of $M_I$ in $\mathcal{M}_{\kappa}(I)$, see clause (f) of Definition E32.1 so $\kappa \geq \theta = \text{cf}(\theta)$

\(\ast\) $\lambda > \chi<^\theta + \theta^+$

\(\ast\) $\bar{a} = (\check{a}_s, s \in I)$ satisfies $\check{a}_s = (F_{i,s}(s) : i < \partial)$ belongs to $^{\chi}(M_s)$ where $F_{i,s}$ is a one-place function symbol for $i < \partial$

\(\ast\) $\lambda \geq \chi<^\theta + \theta^0$ and at least one of the following:

\(\ast\) $\lambda > \chi<^\theta + \chi^\theta$

\(\ast\) $\lambda^0 < 2^\lambda$ and $\text{cf}(\lambda) > \partial$
Remark 3.40. 1) In the cases $M_I = \text{EM}_r(I, \Phi), |\tau_\Phi| \leq \chi, \ell g(\bar{a}_s) = \partial$, clearly $M_I$ is weakly full $\varphi(\bar{x}, \bar{y})$-represented in $\mathcal{M}_{\chi, \theta}$ by some $f$, $f(\bar{a}_s) = (F_i(1) : i < \partial)$ for $\theta = \aleph_0, \chi = |\tau_\Phi| + \aleph_0$.

2) On “weakly full $\varphi(\bar{x}, \bar{y})$-represented” see Definition 3.28 whenever $\mu < \kappa$. So without loss of generality $2^\lambda = \lambda$.

Proof. Note that, letting $\kappa := \partial^+ + \theta$, (so it is a regular cardinal):

$(*)$ in $M_I$, $\langle \bar{a}_s : s \in I \rangle$ is weakly $(\kappa, < \mu, \varphi(\bar{x}, \bar{y}))$-skeleton like in $M_I$, see Definition 3.28 whenever $\mu \geq \kappa$. So in particular $(*)$ Definition 3.29 holds.

[Why? Assume $A \subseteq M_I$ and $|A| < \mu$, so for each $a \in A$ let $a = \sigma_a(\bar{t}_a), \bar{t}_a \in \theta^+ I$ and let $J = \cup \bar{t}_a : a \in A)$, so $J \subseteq I$ is of cardinality $< \mu$ such that $A \subseteq \langle \sigma(\bar{t}) : i \in \theta^+ J$ and $\sigma$ a $\tau_{\chi, \theta}$-term]. Clearly $J$ is as required.

$(**)$ $\chi \geq \partial$ and of course $\lambda > \chi^\theta + \chi^\theta$.

[Why $(**)$ holds? By the assumption $(A)(g).$]

Hence

$(***) \lambda \geq \chi^\theta + \partial^+ \geq \kappa = \text{cf}(\kappa)$.

We shall use $(*)$, $(**)$, $(***)$, freely. Let us see why the cases below and 3.29 cover all the possibilities.

Why does clause (a) hold?

We have to cover the fine possibilities $\bullet_1 - \bullet_5$ of clause $(A)(g)$.

First, if $(A)(g)\bullet_1$ holds, so $\lambda > \chi^\theta + \chi^\theta$ then clause (b) proved below suffices (this covers $\bullet_1$), so without loss of generality $\lambda \leq \chi^\theta + \chi^\theta$ but $\lambda \leq \chi^\theta + \chi^\theta$ so $\lambda = \chi^\theta + \chi^\theta$.

If $(A)(g)\bullet_2$ holds, so $\lambda^\theta < 2^\lambda$ and $\text{cf}(\lambda) > \partial$ then we shall apply claim 3.29 clause (c); so we have to check the assumptions there. The general assumption of 3.29, holds trivially, e.g. “$\langle \bar{a}_s : s \in I \rangle$ is weakly $(\kappa, \varphi(\bar{x}, \bar{y}))$ skeleton like in $M_I$” holds by $(*)$ above.

Now $(*)_{10}$ of 3.29(c) holds by the general assumption of 3.29 and $(*)_1$ there holds by the present assumption $(A)(g)\bullet_2$ we are dealing with and $(*)_{13}$ holds by $(*)$ above. Note that here we use $\lambda \geq \chi^\theta + \partial^+$ instead $\lambda = \chi^\theta + \partial^+$ this is used below.

Second, let $(\lambda_i : i < \text{cf}(\lambda))$ be strictly increasing with limit $\lambda$, $\lambda_i = \text{cf}(\lambda_i) > \chi^\theta + \partial^+$ by assumption $(A)(d)$, and without loss of generality $\langle 2^\lambda_i : i < \text{cf}(\lambda) \rangle$ is constant (so is constantly $2^\lambda$) or is strictly increasing (still $2^\lambda = \prod_{i < \text{cf}(\lambda)} 2^\lambda_i$). In the former case by Fact 11.41 it suffices to prove the result for $\lambda$; now pedantically $\lambda_i$ does not fall under “second” as $\lambda_i < \lambda = \chi^\theta + \chi^\theta$ but the proof there works. So we so assume that $\langle 2^\lambda_i : i < \text{cf}(\lambda) \rangle$ is strictly increasing. As we are assuming $\chi^\theta < \lambda \leq \chi^\theta$, clearly $\lambda$ is not strong limit, So without loss of generality $2^\lambda_i \geq \lambda,$
and hence $2^\lambda \geq \lambda^\beta$, so $2^{\lambda_1} > \lambda^\beta$. But as $(2^{\mu_i} : i < \cf(\lambda))$ is strictly increasing there is a linear order as in $(A)(g)\bullet$, see \textbf{E59}3.2. So $(A)(g)\bullet$ holds and these cases are treated below.

So under “third”, we assume (in addition to “$\lambda = \chi^\theta + \chi^\beta$” only) $\lambda^\beta < 2^\lambda$. Thus covers $(A)(g)\bullet$.

Third, assume $\lambda^\beta < 2^\lambda$, so as without loss of generality the previous case does not hold, we have $\cf(\lambda) \leq \partial$ and clearly $\partial < \lambda$.

Fourth, note that if there is a linear order $I$ with $\geq \lambda$ Dedekind cuts with both cofinalities $\geq \kappa$ and $2^{|I|} < 2^\lambda$ then we are done as in claim \textbf{E59}29 clause (f).

Clause (b):

The proof splits to cases (A)-(F), we give more cases than necessary in order to present some proofs first in easier form.

They suffice. To show this we now show that all cases are covered. Recall that $\lambda > \chi^\theta + \chi^\beta$ so as $\kappa = \theta + \partial^+$, this means that $\lambda > \chi^\kappa$. Furthermore, $\lambda$ is regular; if not covered by clause (F) then necessarily $\lambda \leq \chi^\kappa + \chi^\kappa + (2^\beta)^{\kappa+}$, hence if also not covered by case D, then $\lambda \neq \kappa^+$, so $\lambda > \kappa^+$ hence $\chi^\theta + \chi^\beta < \lambda = \cf(\lambda) \leq (2^\beta)^{\kappa+}$ but $\beta < 2^\beta, \lambda \in \{(2^\beta)^{\kappa+}, (2^\beta)^{\kappa+}\}$ also $2^\kappa = 2^\beta + 2^\beta < \lambda$ so $(\forall \mu < \lambda)(\mu^\kappa < \lambda)$ hence case C applies.

Second, assume $\lambda$ is singular and let $\langle \mu_i : i < \cf(\lambda)\rangle$ be an increasing sequence of regular cardinals with limit $\lambda$ such that $M_i > \chi^\kappa + \chi^\beta$ and $\mu_{i+1} > \mu_i^{\kappa+}$. If $(\forall i < \cf(\lambda))(\mu_i^\kappa < \lambda)$ then without loss of generality $(\forall i)(\forall \mu < \mu_i)(\mu^\kappa < \mu_i)$ hence we can apply case F; so without loss of generality for some $\mu < \lambda, \mu^\kappa < \lambda_\lambda$.

Let $\mu_i = \min(\mu : \mu^\kappa \geq \lambda)$, so as $\lambda > \chi^\kappa$ hence $\mu_* < \lambda, \mu_*$ is singular $> \chi^\kappa$ then let $\langle \mu_i^* : i < \cf(\mu_*)\rangle$ be increasing, each $\mu_i^*$ is regular $> \chi^\kappa$ and $(\forall \mu < \mu_i^*)(\mu^\kappa < \mu_i)$ If $2^\mu = 2^\beta$ then $2^\mu = \prod_i 2^{\mu_i}$ and apply again Case F. So assume $2^\mu < 2^\lambda$.

Case A: $\lambda^\beta = \lambda$ or $\lambda^\kappa > 2^\lambda$.

As $\kappa = \partial^+ + \theta < \lambda$ by (*) above we can apply \textbf{E59}29 case (a) or case (b) and get $\hat{\lambda}(\lambda, K_\lambda) = 2^\lambda$.

Case B: $\lambda^\beta < 2^\lambda$ and $\cf(\lambda) > \partial$ and we get $\hat{\lambda}(\lambda, K_\lambda) = 2^\lambda$.

By \textbf{E59}29 case (c) (and (*) above), as in the proof of case (a), “second”.

Case C: $\lambda$ is regular, $(\forall \mu < \lambda)(\mu^\kappa < \lambda), \lambda \geq \kappa^+$.

Let $S_0 = \{\delta < \lambda : \cf(\delta) \geq \kappa\}$ and let $h_0$ be the function with domain $S_0$ and constant value $\chi^\beta$. Let $J^{[\kappa]}$ be a linear order of cardinality $\kappa$ such that $\alpha < \kappa \Rightarrow J^{[\kappa]} \times (\alpha + 1) \cong J^{[\kappa]} \cong J^{[\kappa]} \times ((\alpha + 1)^*)$. (e.g. let $J$ be a $\kappa$-dense strongly $\kappa$-homogeneous linear order, hence $\alpha < \kappa \Rightarrow J \times (\alpha + 1) \cong J \cong ((\alpha + 1)^*)$, and by the Löwenheim-Skolem argument there is a dense $J' \subseteq J$ of cardinality $\kappa$ with this property, alternatively use \textbf{E59}38, 2.6=\textbf{Lb60}(5)).

Why? By \textbf{E59}3 above for a function

$$h : S_0 \rightarrow \{\mu : \mu \text{ is a regular cardinal, } \kappa \leq \mu < \lambda\}$$

let $I_h$ be the linear order with the set of elements

$$\{(\alpha, \beta, t) : \alpha < \lambda + \kappa, t \in J^{[\kappa]} \text{ and } \beta < h(\alpha) \text{ if } \alpha \in S_0, \beta < \kappa \text{ otherwise}\}.$$
The order is:

\((\alpha_1, \beta_1, t) \leq (\alpha_2, \beta_2, t_1)\) if and only if

\(\alpha_1 < \alpha_2\), or
\(\alpha_1 = \alpha_2\) and \(\beta_1 \geq \beta_2\), or
\(\alpha_1 = \alpha_2\) and \(\beta_1 = \beta_2\) and \(t_1 < t_2\).

Now

\(\square\) \(M_{I_h}\) semi \(\kappa\)-obeys the pair \((h, (\varphi(\bar{x}), \bar{y}))\) exactly (see Definition 3.30).

First we prove "obeys". So (see Definition 3.30(5) with \(\mu = \lambda\)) let \(\bar{b}_\alpha \in \sigma^\delta(M_I)\) for \(\alpha < \lambda\). So for some sequence \(\bar{\sigma}^\delta\) of \(\sigma\)-terms \(\bar{b}_\alpha = \sigma^\delta(\bar{p}_\alpha)\) with \(\bar{p}_\alpha \in \kappa^\delta(I_h)\) \(\zeta^* < \kappa, u \subseteq \zeta^*\), and for some stationary set \(Y \subseteq \{\delta < \lambda : cf(\delta) = \kappa\}\) and term \(\sigma^\delta\) we have

\(\circ \) \(\alpha \in Y \Rightarrow \bar{\sigma}^\delta = \sigma^\delta, \ell g(\bar{t}) = \zeta^*\), order type of \(I \upharpoonright \bar{t}^\delta\) is constant, and \(\bar{t}^\delta \upharpoonright u = \bar{t}^\delta\) and

\(\circ \) \(e \in \zeta^* \setminus u \Rightarrow\) the sequence \(\{\bar{t}^\delta : \alpha \in Y\}\) is \(\langle I \rangle\)-increasing

\(\circ \) \(\exists\) the truth value of \(\bar{t} = I^\delta_1 <_{I_h} I^\delta_2\) for \(\alpha_1, \alpha_2 \in Y\) and \(\epsilon, \delta < \zeta^*\) depend just on the truth values of \(\alpha_1 < \alpha_2, \alpha_2 < \alpha_1\) and the values of \(\epsilon, \delta\).

We define a function \(H\) from \(\lambda^>(|M|)^{|\lambda|}\) to \(|M|)^{|\lambda|}\) by: given \(\langle A_j : j < i\rangle\), with \(A_j \subseteq M_{I_h}\) increasing, \(|A_j| < \mu\) let

\(\gamma = \gamma_{A_i} = \text{Min}\{\gamma : A_j \subseteq \{\sigma^\delta(\bar{t}) : \bar{t} \in \kappa^>(\gamma \times \delta \cap I_h)\}\}\) and

\((\forall j \leq i) \bar{t}^j \subseteq \gamma \times \delta \cap I_h\).

Let \(A_i \in |M_{I_h}|^{|\lambda|}\) be increasing continuous, \(H(\langle A_j : j < i \rangle) \subseteq A_{i+1}\), and let

\(\mathcal{C} = \{\delta \leq \lambda : (\forall \alpha, \beta)(\alpha < \delta \cap (\alpha, \beta) \in I_h \Rightarrow \beta < \delta)\) and

\((\forall i)(\forall \delta) (\forall \beta < \delta \Rightarrow \beta \in \delta)\) and \(\alpha < \delta\) and \(i \in \delta\) and \(\delta = \sup(\delta \cap Y)\) and

\(\in \in \sigma \setminus u \Rightarrow (\forall i)(\forall \delta) (\forall \bar{t}^i : \delta \in \delta \times \delta \cap J[I^\delta_1 \equiv i < \delta])\).

Clearly \(\mathcal{C}\) is a club of \(\lambda\). Now let \(\delta \in S \cap \mathcal{C}\). We can choose \(\beta(i) \in Y\) for \(i < cf(\delta)\) increasing with limit \(\delta\). By the definition of representable clearly \(\{\beta(i) : i < cf(\delta)\}\) as required from \(\langle A_i : i < cf(\delta)\rangle\) in Definition 3.30(1), and so \(p^* = p^*_{M_{I_h}}(\bar{b}_\beta(i) < cf(\delta))\) is well defined.

Now

\((*)_0\) if \(B \in |M|^{<h_1(\delta)}\) then \(p^* \upharpoonright (A_\delta \cup B)\) is realized in \(N\).

[Why? Let \(I^* \in |I|^{<h_1(\delta)}\) be such that

\(B \subseteq \{\sigma(\bar{t}) : \sigma\) is a \(\tau_{\chi, \sigma}\)-term and \(\bar{t} \in \kappa^>(I^*)\}\).

We can find \(\beta^* < h_1(\delta)\) such that

\((\alpha', \beta', \bar{t}') \in I' \setminus (\delta \times \delta \times J[I]) \Rightarrow \beta' < \beta^*\).

Now we can choose \(\bar{t}^{\otimes} \in \kappa^> I\) such that \(\bar{t}^{\otimes} \upharpoonright \bar{u} = \bar{t}^{\otimes} \upharpoonright \bar{u}\), and

\(\check{\delta}_0 = \check{\delta}(\bar{t}^{\otimes})\) is well defined.
\[ \epsilon \in \partial \setminus u \Rightarrow t^\sigma_e \in \{ \delta \} \times \{ \beta^* \} \times J^{[\kappa]} \]

and

\[ \epsilon, \zeta < \partial \Rightarrow [t^\sigma_e < t^\sigma_e \equiv t^*_e < t^*_e], \]

possible by the choice of \( J^{[\kappa]} \). By “represented” and the definition of \( p^* \), clearly \( \sigma^*(\mathcal{P}) \) realizes \( p^* \upharpoonright (A_\delta \cup B) \), so \((*)_0 \) holds.]

Now \((*)\) tells us that \( M_{t^*_e} \) semi-\( \kappa \)-obeys \((0, h_1, \phi(x, y)) \). As for the “exactly,” it is enough to find \( \langle b_\alpha : \alpha < \mu \rangle \) exemplifying that, i.e. that for each unbounded \( S \subseteq \mu, \langle b_\alpha : \alpha \in S \rangle \) fulfill the demand there more then needed it follows by Fact \( (*)_{\lambda, \mu} \) from above.

Case D: \( \lambda = \kappa^+ \gg \chi^\theta \).

Similar to Case C, but we have to allow \( h(\delta) \) to be \( \kappa^+ = \lambda \) in addition to \( \kappa \). So \( I_{h_{,}} \), defined similarly using \( J^{[\lambda]} \) (not \( J^{[\kappa]} \)), is no longer \( \lambda \)-like, \( b_\alpha \in \delta(M_{h_{,}}) \), if the rest is not obvious look at the proof of Case E.

Case E: \( 0 < \gamma^* \) (so possibly \( \gamma^* = 1 \), \( \chi^{<\kappa} + |\alpha| < \mu_i < \lambda \), \( \mu_i \langle i < \gamma^* \rangle \) strictly increasing, each \( \mu_i \) regular, \( \mu_{i+1} > \mu_i^{++}, \mu_i > \chi + \partial^+ + \theta \), \((\forall \mu < \mu_i)\mu^{<\kappa} < \mu_i, \prod \mu^i = 2^\lambda \) (without the last assumption we just get a smaller number of models; note that if \((\forall \alpha < \lambda) (\chi + |\alpha|^{<\kappa} < \lambda) \), then there is such \( \langle \mu_i : i < \alpha \rangle \) )

Let \( J^i \cong J^{[\mu^i_+]} \) for \( i < \alpha^* \) be from Fact \( (*)_{\lambda, \mu} \) above, and for each \( i < \gamma^* \) define \( J_h \in K^{\alpha^*}_{\mu^i_+} \), for \( h : \{ \delta < \mu_i^{++} : \operatorname{cf}(\delta) = \mu_i^{++} \} \rightarrow \{ \mu_i^{+++}, \mu_i^{++} \} \) to be \( \sum_{\gamma \in \mu^{++}_{i+3} \setminus \kappa} (J^i_h)^\gamma \),

where: \( \mu_i^{++} + \kappa \) is ordinal addition, the \( J^i_h \) are pairwise disjoint, \( J^i_h \) is isomorphic to \( J^i \) except when \( h(\zeta) \) is well defined and equal to \( \mu_i^+ \), then \( J^i_h \) is isomorphic to \( J^i \times (\mu_i^+)^+ \).

Lastly, for every

\[ \bar{h} \in \prod_i \{ h : \operatorname{Dom}(h) = S_i = \{ \delta < \mu_i^{++} : \operatorname{cf}(\delta) = \mu_i^+ \}, \text{ } h \text{ as above } \}, \]

we let \( I_{h_{,}} := \sum_i J_{h_i} + \lambda \times J^{[\kappa]} \).

For each \( i < \alpha \) we have to prove that \( h_i/\mathcal{G}_{\mu^{+++}_i} \) is an invariant of the isomorphic type of \( M_{h_{,}} \). For this it is enough to prove, for each \( \gamma_* < \gamma^* \), that

\((*) \) \( M_{h_{,}} \) exactly semi \( \kappa \)-obeys \((0, h_{,}, \phi) \).

It is enough to prove “semi-\( \kappa \)-obeys \((0, h_{,}, \phi) \)” , as then the exactness follows by Fact \( \alpha \) above. Let \( b_\alpha \in \delta(M_{h_{,}}) \) for \( \alpha < \mu_i^{+++} \), so \( b_\alpha = \sigma^*(\mathcal{P}) \), \( \mathcal{P} \in \kappa^{<\gamma} (I_{h_{,}}) \). We can find a stationary set \( Y \subseteq \{ \delta < \mu_i^{+++} : \operatorname{cf}(\delta) = \kappa \} \) such that

\[ \alpha \in Y \Rightarrow \delta^\alpha / \mathcal{G}^\alpha = \sigma^* \wedge \ell g(\mathcal{P}) = \epsilon^* \]

as \( \{ (\epsilon, \zeta) : t^\sigma_e < \zeta^\alpha \} = v, u_{\gamma, \gamma} = \{ \epsilon < \epsilon^* : t^\sigma_e \in J_{h_{,}} \} = u_{\gamma} \). By clauses \((i)+(h)\), without loss of generality \( (\mathcal{P} : \alpha \in Y) \) is order indiscernible, as in the proof of Case C.
So for each $\epsilon < \epsilon^*$, $\langle t^\alpha_ : \alpha \in Y \rangle$ is constant, or strictly increasing, or strictly decreasing, and for some $\gamma < \gamma^*$ they are all in on one $I_{b_0}$, moreover if $\langle t^\alpha_ : \alpha \in Y \rangle$ is not constant necessarily $\gamma \geq \gamma^*$. So if $\langle t^\alpha_ : \alpha \in Y \rangle$ is strictly increasing, $\delta < \mu^+_{\gamma^*}$, cf$(\delta) = \mu^*_{\gamma^*}$, then

$$cf(I^*_b \mid \{ t : t < t^*_\alpha \text{ for every } \alpha \in Y \})$$

is $\mu^*_\gamma$ or $\mu^+_{\gamma^*}$ when $\epsilon \in u_\gamma$, so is $\geq \mu^+_{\gamma^*}$ except when $\epsilon \in u_\gamma$, and $h(\delta) = \mu^*_\gamma$. The situation is similar when $\langle t^\alpha_ : \alpha \in Y \rangle$ is strictly decreasing, except that now $\epsilon \in u_\gamma$ is impossible.

**Case F:** $\lambda$ is regular $> \chi_\theta + \chi^3 + \kappa^+$, without loss of generality $\lambda = (2^3)^+$. (Why the without loss of generality? Otherwise Case C applies.)

First proof:

Let

$$S = \{ \delta < \lambda : cf(\delta) = (2^3)^+ \},$$

and for $h : S \to \text{Reg} \cap [\kappa, \lambda)$ we define $I_h$ as in Case C. It suffices to prove

$$(*) \ M_{I_h} \text{ exactly semi } \kappa \text{-obyes } (0, h, \varphi).$$

It suffices to prove $M_{I_h}$ semi $\kappa$-obyes $(0, h, \varphi)$ as the exactly follows by Fact $\alpha$. Let $b_0 \in \theta(M_{I_h})$ for $\alpha < \lambda$ be such that $\langle b_\alpha : \alpha < \lambda \rangle$ is $(\kappa, \varphi)$-skeleton like and let $b_0 = \sigma^a(I^a)$, and we choose a stationary set $Y_0 \subseteq \{ \delta < \lambda : cf(\delta) = \kappa \}$ such that $\alpha \in Y \Rightarrow \sigma^a = \sigma^*$ and $\{ (\epsilon, \zeta) : t^\epsilon_\zeta < t^\alpha_\zeta \} = v, \ell_g(t^a) = \epsilon^* < \kappa$ (but no $\Delta$-system!).

Let $\langle A_i : i < \lambda \rangle, \langle I_i : (\gamma_i \times \delta \times J') \cap I : i < \lambda \rangle, \varphi$ be as there.

For $\delta \in S \cap \text{acc}(C)$ let $Y_1 \subseteq Y \cap \delta \cap \varphi$ be unbounded of order type $cf(\delta)$, and $Y_2 \subseteq Y_1$ be unbounded and $\langle t^\alpha_ : \alpha \in Y_2 \rangle$ be indiscernible ($\text{for } <_{I_0}$) (exists as $\text{otp}(Y_1) = (2^3)^+$).

Let

$$u_0 = \{ \epsilon < \epsilon^* : \langle t^\alpha_ : \alpha \in Y_2 \rangle \text{ is constant} \},$$

$$u_1 = \{ \epsilon < \epsilon^* : \langle t^\alpha_ : \alpha \in Y_2 \rangle \text{ is increasing and } (\forall \beta < \delta)(\exists \alpha \in Y_2)(t^\alpha_ \notin I_\beta) \},$$

$$u_2 = \epsilon^* \setminus u_0 \setminus u_1.$$

Choose $\beta_0 < \beta_1 < \beta_2$ in $Y_2$ such that $\{ t^\alpha_ : \alpha \in Y_1, \epsilon \in u_2 \cup u_0 \} \subseteq I_{\beta_0}$.

For each $\beta \in Y_2 \setminus \beta_2$ define $s^\beta = s^\alpha \in \epsilon'$, $s^\alpha \mid u_0 = \bar{t}^\alpha \mid u_0$ for $\epsilon \in Y_2$, $s^\beta \mid u_1 = \bar{t}^\beta \mid u_1, s^\beta \mid u_2 = \bar{t}^{\beta_2} \mid u_2$. Now we can continue as in Case C when we note

$$(\odot) \text{ if } \beta_3 < \beta_4 \text{ are from } Y_2 \setminus \beta_2 \text{ then } \sigma^*(\bar{t}^{\beta_4}), \sigma^*(s^{\beta_4}) \text{ realize the same } \{ \varphi, \psi \} -$$

$$\text{type over } A_{\beta_3}.$$[Why? Let $d \in \theta(A_{\beta_3})$ so $d = \sigma'(\bar{t})$, $\bar{t} \in \kappa^>(I_{\beta_3})$. If, e.g.,

$$M_{I_h} \models \theta[\sigma^*(\bar{t}^{\beta_4}), d] \equiv -\theta[\sigma^*(s^{\beta_4}), d]$$

then

$$M \models \theta[\sigma^*(\bar{t}^{\beta_4}), \sigma'(\bar{t}')] \equiv -\theta[\sigma^*(s^{\beta_4}), \sigma'(\bar{t}')]$$

So $(\odot)$ holds.]
Now we can find $\mathcal{P}' \in s^+(I_{\beta_1})$ such that $\mathcal{P}''$, $\mathcal{P}$ realizes the same quantifier free type (in $\mathcal{I}$) over $I_{\beta_1}$, hence over $(\mathcal{P}'' \setminus (u_0 \cup u_2)) \setminus (u_0 \cup u_2)$. Hence

$$M_{I_S} \models \forall \sigma^* (x, y) \equiv \neg \forall \sigma^* (x, y').$$

Similarly, $\mathcal{P}''$, $\mathcal{P}$ realize the same quantifier free type (in $\mathcal{I}$) over $I_{\beta_1}$, hence

$$M_{I_S} \models \forall \sigma^* (x, y) \equiv \forall \sigma^*(x, y'),$$

so together

$$M_{I_S} \models \forall \sigma^* (x, y) \equiv \neg \forall \sigma^*(x, y').$$

But this contradicts the choice of $C$ (as $Y \subseteq C$).

**Conclusion 3.41.** 1) Suppose $\psi \in L_{\kappa^+, \kappa_0} (\tau_1)$, $\tau \subseteq \tau_1$, $\varphi(x, y) \in L_{\kappa^+, \kappa_0} (\tau)$, $\ell g(x) = \ell g(y) = \partial \subseteq \chi$, and $\psi$ has the $\varphi(x, y)$-order property that is for every $\mu$ for some model $M$ of $\psi$ there are $\bar{a}_i \in M$ (for $i < \mu$) such that

$$M \models \varphi[\bar{a}_i, \bar{a}_j] \iff i < j.$$

Then for every $\lambda$ such that $\lambda > \chi^\partial$ or $\lambda > \chi \land 2^\lambda > \lambda^\partial$, $\psi$ has $2^\lambda$ models of cardinality $\lambda$ with pairwise non-isomorphic $\tau$-reducts.

2) If (A) then (B) where:

(A) (a) $\psi \in L_{\kappa^+, \kappa_0} (\tau)$
(b) $\varphi(x, y) \in L_{\kappa^+, \kappa_0} (\tau)$, for $\ell = 1, 2$, $\ell g(x) = \ell g(y) = \partial$
(c) $\tau_0 = \tau_1 \cap \tau_2 = \tau_1 \cap \tau = \tau_2 \cap \tau$
(d) $\{\varphi_1(x, y), \varphi_2(x, y)\}$ has no model
(e) $\psi$ has the $\{\varphi_1, \varphi_2\}$-order property, which means that:

(*) for every $\alpha$ there is a $\tau_0$-model $M$ and $\bar{a}_\beta \in \tau_0 M$ for $\beta < \alpha$, such that: if $\beta < \gamma < \alpha$ then

(i) for some expansion $M'$ of $M$, $M' \models \varphi_1[\bar{a}_\beta, \bar{a}_\gamma]$,  

(ii) for some expansion $M'$ of $M$, $M' \models \varphi_2[\bar{a}_\beta, \bar{a}_\gamma]$. 

(f) Let $\varphi_1(x, y) = (\exists_1 R, \ldots, R_{\kappa_1}) \varphi_1(x, y)$; it is a formula in the vocabulary $\tau_0$ (but of second order).

(B) (a) if $\lambda$ satisfies $\lambda > \chi^\partial$ or $\lambda > \chi \land 2^\lambda > \lambda^\partial$, then $\hat{H}_\nu (\lambda, \psi) = 2^\lambda$ i.e., there are $2^\lambda$ non-isomorphic $\tau$-models of $\psi$ of cardinality $\lambda$, in fact even their $\tau_0$-reducts are not isomorphic;

(b) for $\lambda \geq \chi$ there are $\langle M_j : J \in (\kappa^\omega) \rangle$, $M_j$ a model of $\psi$ of cardinality $\lambda$ with a weakly $(\partial^+, \varphi)$-skeleton like $\langle a_s : s \in J \rangle$, $a_s \in \tau_0 M_j$, fully represented in $A_{\kappa, \kappa_0}$ and $\bar{a}_s = \bar{a}(s)$ for some sequence $\sigma$ of term of $\tau_0 \in \bar{a}(s)$, or even $\bar{a}_s = (F_{i}(s) : i < \partial)$.

**Proof.** 1) Follows from (2), by taking $\varphi(x, y) = \varphi_1(x, y) = \varphi_2(y, x)$.

2) By 1.18(3), 1.23 there is $\Phi$, proper for the class of linear orders (see Definition 1.8) such that for every linear order $I$, EM$_\tau (I, \Phi)$ is a model of $\psi$ of cardinality $\chi + |I|$ with skeleton $\langle a^*_t : s \in I \rangle$ for $t \in I$, $a_t$ is a sequence of length $\partial$ of members of EM$_\tau (I, \Phi)$, in fact is $\bar{a}(a^*_t)$ for a fixed $\sigma$, such that for $s \neq t \in I$: 

Definition 3.44. For a linear order \( I \) we can use (a) or (a)+(b) or (a)+(b)', where

(a) replace weakly in “weakly \( \ldots \) skeleton like” by pseudo (including the definitions) and all claims remain true;
(b) restricting ourselves to \( \lambda \geq 2^{\kappa} \), we can replace linear orders by strongly \( \kappa \)-dense linear order (see below);
(b)' we can demand that all our linear orders are \( \theta \)-stable and almost \( \theta \)-homogeneous, see Definition 3.37, i.e. [Sh:E62, 2.15=Lb56].

Remark 3.42. Note that if we use strongly \( \kappa \)-homogeneous \( J^{[\kappa]} \) and \( M_I \) is weakly fully represented in \( \mathcal{M}_\theta(I) \) then this form of \( J \) helps to “eliminate quantifiers” is \( \mathcal{M}_\theta(I) \), i.e. \( \text{tp}(\bar{\sigma}, I, \emptyset, M_I) \) is determined by \( \bar{\sigma} \) and the order of \( I \) if \( I \in J^{[\kappa]} \). The order \( I^{[\kappa]} \) is not really so homogeneous but it close too, see more in [Sh:E62, §2].

Claim 3.43. In the theorems above in the assumption we can restrict ourselves to linear order \( I \) satisfying

\((\ast)_1\) (a) for every infinite \( J \subseteq I \), the number of Dedekind cuts of \( J \) realized by elements of \( I \) is at most \(|J| \) (i.e., stable in \( \theta \) for every \( \theta \)),
(b) for every infinite \( J_0 \subseteq I \) there is an \( I_1 \), satisfying \( J_0 \subseteq J_1 \subseteq I \) such that \(|J_0| = |J_1| \) and: if \( s, t \in I \setminus J_1 \) realize the same Dedekind cuts of \( J_1 \) then there is an automorphism \( h \) of \( I \) over \( J_1 \) (i.e. \( h|J_1 = \text{id}_{J_1} \)) mapping \( s \) to \( t \) (i.e., almost homogeneous for every \( \theta \)). See more in Definition 3.38, i.e. [Sh:E62, 2.16=Lb60] and [Sh:E62, 2.16=Lb60].

Proof. By [Sh:E62, 2.15=Lb56].

We may weaken a little the definition of weakly \( \kappa \)-skeleton like (Definition 3.1(1)).

Definition 3.44. 1) We say \( (\bar{a}_s : s \in J) \) is pseudo \( \kappa \)-skeleton like for \( \Lambda \) when: for every \( \varphi(\bar{x}, \bar{a}) \in \Lambda \) and a Dedekind cut \((I_0, I_1)\) of \( I \) such that \( I_1 \neq \emptyset \Rightarrow \text{cf}(I_1) \geq \kappa \) and \( I_2 \neq \emptyset \Rightarrow \text{cf}(I_2) \geq \kappa \) there are \( J_0, J_1 \) such that

\((\ast)_1\) \( J_0 \) is an end segment of \( I_0 \) non empty if \( I_0 \neq \emptyset \),
\((\ast)_2\) \( J_1 \) is an initial segment of \( I_1 \), non empty if \( I_1 \neq \emptyset \),
\((\ast)_3\) if \( s, t \in J_0 \cup J_1 \) then \( M \models \varphi(\bar{a}_s, \bar{a}) \equiv \varphi(\bar{a}_t, \bar{a}) \); clearly this is a weaker demand than the “weakly” version.

2) Similarly we adopt Definition 3.1(2),(4).

What is the difference? E.g., for \( \kappa = \aleph_0 \), \( J_4 \) instead of being countable it may be a Suslin order or Specker order.

Claim 3.45. We can through all this section ask (a) or (a)+(b) or (a)+(b)', where
Definition 3.46. 1) A linear order $I$ is $\kappa$-homogeneous when $\text{cf}(I) \geq \kappa$, $\text{cf}(I^*) \geq \kappa$ for any subsets $J_0$, $J_1$ of $I$ of cardinality $< \kappa$ (possibly empty) satisfying $(\forall s_0 \in J_0)(\forall s_1 \in J_1)(s_0 <_I s_1)$ there is $t \in I$ such that $(\forall s_0 \in J_0)(s_0 <_I t)$ and $(\forall s_1 \in J_1)(t <_I s_1)$.

2) A linear order $I$ is strongly $\kappa$-dense when it is $\kappa$-dense and every partial one-to-one function from $I$ to $I$ of cardinality $< \kappa$ can be extended to an automorphism.

3) A linear order $I$ is $\theta$-stable if for every $J \subseteq I$ of cardinality $\leq \theta$, the number of Dedekind cuts of $J$ induced by elements of $I$ is at most $\bar{\theta}$.

Proof. Straightforward, we rely on [Sh:E62, 2.16=Lb60(5)].
